1 引言

燃烧为人类的生产和生活提供所需的能源, 目前世界上超过 80% 的能源都是通过燃烧获得的^[1]。超燃冲压发动机^[2-3]、火箭发动机^[4-5]、燃气轮机^[6-7]、内燃机^[8]等都是通过燃料在发动机燃烧室内的燃烧获得维持发动机正常工作的推力。因此, 深入研究燃烧机理, 增强燃烧性能调控, 有助于提高燃烧效率, 降低燃烧污染物排放^[9], 优化发动机的推力性能。

理论模型^[10-12]、数值计算^[13-14]和实验测量^[15-20]是研究发动机燃烧机理的三种关键手段。燃烧实验测量技术可为完善燃烧理论模型和改进数值计算方法提供可靠的校验, 实验测量获得的火焰结构、组分浓度、当量比、火焰温度和流场速度等重要参数, 有助于揭示发动机燃烧流场的特征和内在机制, 为发动机燃烧室的设计和燃烧性能的优化奠定基础^[21]。

传统的实验测量方法为接触式物理探针法, 如热电偶测温、热线风速仪测速。物理探针法直接将探测器侵入燃烧流场中, 会造成流场、传热、催化、淬灭等干扰。火焰自发辐射成像(如高速摄影)为非接触式光学测量方法, 能记录火焰结构及其动态演化过程且不会干扰燃烧流场, 但自发辐射图像为路径

积分的结果, 没有空间分辨率, 且难以获得火焰的定量参数信息。

与物理探针法和自发图像成像法相比, 激光诱导荧光(LIF)技术具有非扰动、实时原位测量、组分选择性强、灵敏度好、时空分辨率高等优点^[22]。在 LIF 测量时, 将具有特定波长的激光导入燃烧流场中, 待测组分吸收激光后向上能级跃迁, 随后再向下降能级跃迁时向外辐射出荧光, 通过分析、处理和标定荧光信号, 可获得火焰的瞬时结构、组分浓度、当量比、火焰温度和流速等信息。

自 Kychakoff 等^[23]用 LIF 成像火焰瞬时结构以来, LIF 技术被广泛应用于燃烧诊断中, 且应用场合和测量参数还在不断拓展。应用场合从实验室基础层流和湍流火焰的诊断^[24-27]逐步发展到发动机燃烧室高温、高压和高速的复杂燃烧流场诊断^[28-31]; 测量参数从定性成像火焰瞬时结构和燃料分布^[32-34]发展到浓度^[35-36]、温度^[37-39]、流速^[40]等重要参数的定量测量, 且逐步向高速^[41-42]、三维(3D)^[43-44]和多参数测量^[45-46]发展。

本文结合国防科技大学 LIF 技术燃烧诊断方面的研究工作, 综述了 LIF 技术在燃烧诊断中的研究进展及其在发动机燃烧流场测量中的应用。首先介绍 LIF 技术的基础理论, 然后论述了 LIF 技术在

测量火焰瞬时结构成像、组分浓度、当量比、火焰温度和流速等方面的研究进展,最后对 LIF 技术的发展趋势进行了展望。

2 平面激光诱导荧光基础理论

物质的电子能级、振动能级和转动能级等结构具有指纹识别作用,不同物质或同一物质在不同温度、速度和压力环境中的能级结构、粒子数分布均存在差异。燃烧化学反应产生的中间产物(如 CH、OH 和 CH₂O)具有特定的能级结构,这些组分吸收特定波长的激光光子能量后会被激发至高能级,位于高能级的粒子会返回低能级并发出具有光谱特征的 LIF 信号。LIF 能级跃迁示意图如图 1 所示,其中, v' 为振动能级。根据 LIF 信号的激发光谱、荧光光谱和荧光强度等信息可获得燃烧过程中的火焰瞬时结构、组分浓度、火焰温度等特征参数。

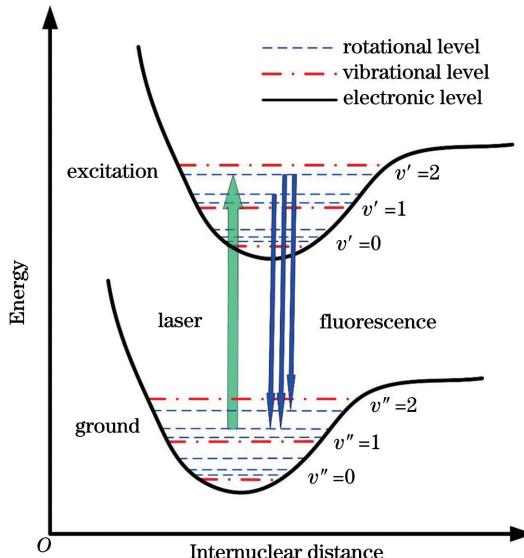

图 1 LIF 能级跃迁示意图

Fig. 1 Schematic diagram of the energy level transition of the LIF

根据单光子二能级结构模型^[47],得到 LIF 信号的强度 F 为

$$F = \frac{h\nu}{c} \frac{\Omega}{4\pi} \cdot l \cdot A \cdot N_1^0 \cdot \frac{B_{12}}{B_{21} + B_{12}} \frac{A_{21}}{1 + I_{\text{sat}}^\nu / I_\nu}, \quad (1)$$

式中, $h\nu$ 为荧光光子的能量, h 为常量, ν 为频率, c 为真空中的光速, Ω 为信号接收立体角, A 为激光的聚焦面积, l 为激光沿光轴能观测到的长度, N_1^0 为激光激发前的下能级布居, B_{21} 和 B_{12} 分别为受激吸收和发射的爱因斯坦系数, A_{21} 为较高能级粒子的自发发射率, I_ν 为激光光谱强度, $I_{\text{sat}}^\nu =$

$c(A_{12} + Q_{21})/(B_{21} + B_{12})$ 为饱和光谱强度,其中, Q_{21} 为淬灭速率。在弱激发状态,即 $I_\nu \ll I_{\text{sat}}^\nu$ 时,(1) 式可表示为

$$F = \frac{h\nu}{c} \frac{\Omega}{4\pi} \cdot l \cdot A \cdot N_1^0 \cdot B_{12} \cdot I_\nu \cdot \frac{A_{21}}{A_{21} + Q_{21}}。 \quad (2)$$

在强激发状态达到饱和,即 $I_\nu \gg I_{\text{sat}}^\nu$ 时,(1) 式可表示为

$$F = \frac{h\nu}{c} \frac{\Omega}{4\pi} \cdot l \cdot A \cdot N_1^0 \cdot A_{21} \cdot \frac{B_{12}}{B_{12} + B_{21}}。 \quad (3)$$

由(2)式和(3)式可知,通过测量荧光强度 F 能获得组分浓度 N_1^0 。但在弱激发状态,需要考虑淬灭速率 Q_{21} 对组分浓度定量测量的影响。在饱和状态,淬灭速率 Q_{21} 的影响可忽略。

双线 LIF 法通过测量上下能级的粒子数分布获得组分的温度信息,利用两束不同波长的激光激发同一物质的上下能级,收集两束激光激发后不同波长的荧光信号,再通过数据处理和标定等获得温度信息。双线 LIF 法测得的温度可表示为^[48]

$$T = \frac{-\Delta E/k}{\ln \frac{F_1}{F_2} + \ln \frac{I_2}{I_1} + 4 \ln \frac{\lambda_1}{\lambda_2} + \ln C}, \quad (4)$$

式中, ΔE 为上下能级差, k 为玻尔兹曼常数, F_1 和 F_2 分别为两束荧光信号的强度, I_1 和 I_2 分别为两束激发激光的强度, λ_1 和 λ_2 分别为两束荧光信号的波长, 常数 C 可通过标定已知温度的标准燃具获得。

为了将 LIF 技术应用于二维(2D)成像,通常利用光学透镜组将激光束制作成光片,形成平面 LIF (PLIF)。PLIF 光片的形成示意图如图 2 所示,其中,CL 为柱面凹透镜,SL 为球面凸透镜,激光片的厚度通常为 100 μm 量级。PLIF 可将测量范围拓

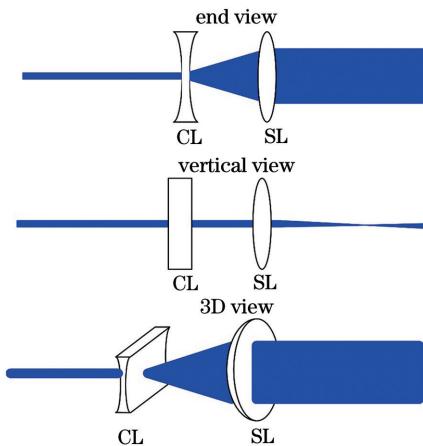

图 2 PLIF 光片的示意图

Fig. 2 Schematic diagram of the PLIF laser sheet

展至二维空间的特定平面,不受同一方向上不同截面自发辐射光信号空间积分效应的影响,且具有较高的空间分辨率。常用PLIF激光器的脉冲宽度约为10 ns,相机的曝光时间可控制在几十纳秒量级,可以很好地滤除火焰的自发辐射光,且不受自发辐射时间上积分效应的影响。因此,PLIF可以高时空分辨成像火焰结构、燃料分布和火焰温度。

3 PLIF 成像火焰瞬时结构

碳氢燃料燃烧过程中产生的最重要中间产物(如甲醛CH₂O、次甲基CH、羟基OH)可以作为火焰瞬时结构的示踪物。CH₂O为火焰预热区的示踪物,CH为火焰反应区的示踪物,OH为火焰产物区的示踪物。实际发动机中的燃烧都是湍流燃烧,存在燃烧化学反应与湍流流场的强耦合。在湍流作用下,火焰瞬时结构会发生扭曲、褶皱、破碎、局部熄火和重燃等变化,通过PLIF技术成像火焰瞬时结构有助于研究燃烧和湍流的相互作用机理。

3.1 单组分PLIF

PLIF通过高时空分辨成像CH₂O、CH、OH的二维分布,呈现火焰预热区、反应区和产物区的瞬时结构^[22]。表1为CH₂O、CH、OH与其他常用于燃烧诊断的荧光组分以及PLIF技术方案^[49-60]。

图3(a)为单组份PLIF实验系统示意图,主要由激光器、光路、探测器和时序同步控制器组成。图3(b)~图3(f)分别为开放式小型射流火焰HCO、CH₂O、CH、OH和CH₃单组分PLIF成像火焰瞬时结构的结果,可实现湍流火焰预热区、反应区、产物区和放热区的高时空分辨可视化^[56, 61-63]。就PLIF成像火焰瞬时结构而言,主要包括改进常见组分(如CH₂O、CH、OH)的激发方案、拓展测量的组分范围(如醛基HCO、氰基CN、H原子和O原子)以及开发光解-LIF(PF-LIF)技术。Carter等^[64]提出了基于CH中C-X能级跃迁的荧光激发方案,可在提高CH荧光信号信噪比的同时降低所需激光脉冲的能量,从而利用现有激光器技术实现小型火焰CH PLIF的10 kHz频率测量,其中,激光单脉冲能量为0.2 mJ。Zhou等^[56]提出了适用于中低当量比预混火焰的HCO PLIF技术,实现了能表征燃烧释热率分布的HCO瞬时成像。Li等^[63, 65]提出了甲基CH₃的PF-LIF技术,利用波长约为213 nm的激光将CH₃光解为CH,然后基于CH PLIF技术对光解产生的CH进行成像;由于光解CH₃产生的CH浓度远远高于火焰原有的CH浓度,获得的荧光信号图像可视为CH₃的二维分布。

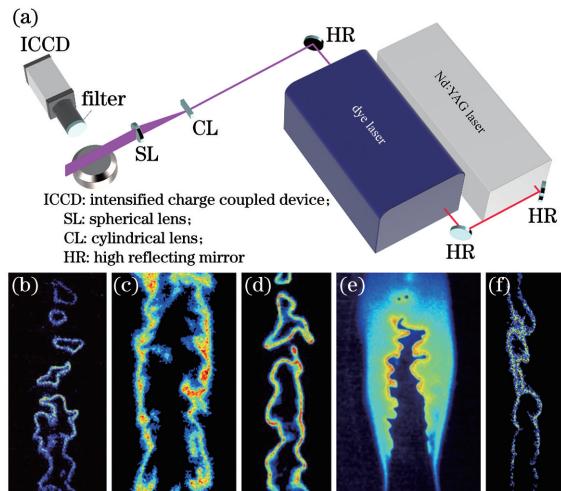

图3 单组分 PLIF 成像的射流火焰。(a) 实验系统; (b) HCO PLIF^[56]; (c) CH₂O PLIF; (d) CH PLIF^[61]; (e) OH PLIF^[62]; (f) CH₃ PF-LIF^[63]

与对开放空间火焰的成像不同,PLIF 成像发动机火焰瞬时结构是在封闭的燃烧室中进行的,需要通过光学窗口引入激发激光,并从光学窗口收集荧光信号。由于荧光信号较弱,需要尽可能地降低壁面反射的激光,限制了激发激光的脉冲能量。发动机的燃烧室需要在高速入口来流条件下,在有限空间内组织燃料与空气的混合、燃烧,燃烧室内反应强度高,火焰背景辐射较强。此外,还存在光学系统无法在线优化等难点。这些因素使 PLIF 成像发动机火焰结构时,需要针对不同的测试工况和测试环境优化技术方案,以提高荧光信号的信噪比。

目前,PLIF 成像发动机火焰结构大多采用 OH PLIF 技术^[30-31,66-72],原因是 OH 在火焰中的浓度相对较大,其荧光效率高、荧光信号波长范围窄且处于紫外波段,受火焰背景辐射干扰小。图 4(a)^[66]与图 4(b)^[31]为国防科技大学直连式超声速燃烧实验台上拍摄并采用 OH PLIF 成像凹腔区域火焰结构的图像。流向成像结果表明,在凹腔内部、凹腔上方的剪切层都存在大量 OH 荧光信号,证明了凹腔的高温回流稳焰机制是有效的;成像结果显示,OH 大量分布于燃料横向射流反转涡旋对的周围,这表明射流引发的流场结构与燃烧室火焰结构存在密切联系。为了获得更精细的 OH 分布图像,Geipel 等^[69]直接用一块焦距为 20 mm 的凸透镜作为相机镜头,单幅图像的视场范围直径约为 6 mm;通过步进电

机和导轨精确控制相机移动,对燃烧室内不同位置的 OH 荧光信号进行高分辨率成像,结果如图 4(c)所示。Tian 等^[72]利用 OH PLIF 对不同工况下超燃冲压发动机内的 OH 分布进行成像,测量结果表明,发动机内的燃烧具有较强的不稳定性。为了使发动机更适合光学诊断,近年来用于光学诊断的发动机存在小型化、透明化的发展趋势^[71]。发动机小型化后,相机得到的单幅图像可捕获更大的区域;透明化后的发动机提供了便利的光学窗口,为三维燃烧诊断技术^[73-74]的应用创造了条件。

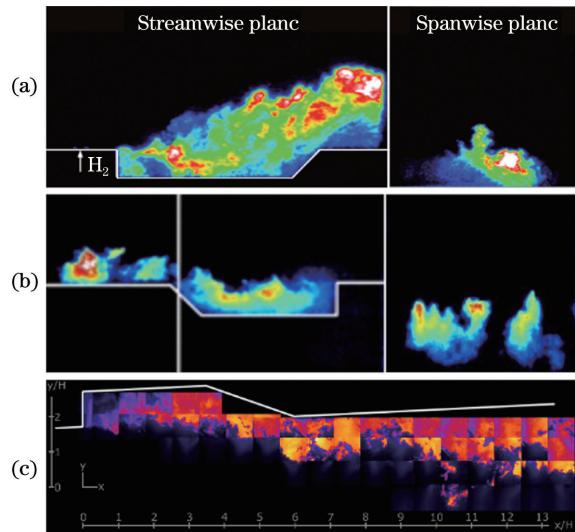

图4 超燃冲压发动机瞬态火焰结构的 OH PLIF 成像。(a) 氢气喷注^[66]; (b) 乙烯喷注^[31]; (c) 乙烯喷注的高分辨率成像^[69]

Fig. 4 Instantaneous flame structure acquired by OH PLIF in scramjet engines. (a) Hydrogen injection^[66]; (b) ethylene injection^[31]; (c) ethylene injection with high-resolution imaging^[69]

尽管 CH PLIF 和 CH₂O PLIF 已广泛用于开放式小型火焰炉的燃烧研究^[18],但其在发动机中的应用仍十分受限,原因是燃烧室内的背景噪声较强,导致荧光信号的信噪比偏低。Micka 等^[75-76]利用 CH PLIF 对发动机燃烧进行研究时发现,仅用窄带滤光片无法消除火焰的辐射背景光;因此,将一台相机放置在燃烧室的另一侧同时拍摄火焰辐射背景图像,通过减背景提高 CH 图像的信噪比。基于 Alexandrite 激光器输出的二倍频(波长约为 387 nm),国防科技大学利用 CH PLIF 对凹腔火焰结构进行成像,结果如图 5(a)^[77]和图 5(b)^[31]所示。可以发现,CH 荧光信号主要分布于凹腔剪切层附近,这表明凹腔高温产物被卷入剪切层,对剪切层火焰起到稳定作用,如图 5(c)所示。CH 反应层厚度

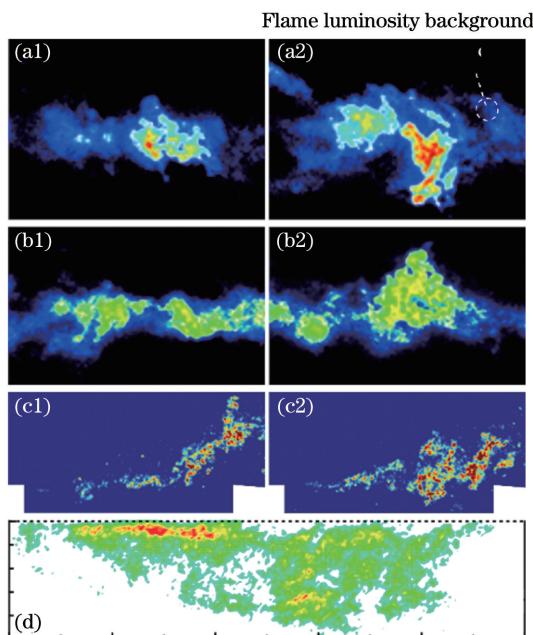

图 5 不同 PLIF 方法得到的瞬态火焰结构。(a)CH PLIF^[77]；(b)CH PLIF^[31]；(c)CH PLIF^[76]；(d)CH₂O PLIF^[78]

Fig. 5 Instantaneous flame structures obtained by different PLIF methods. (a) CH PLIF^[77]；(b) CH PLIF^[31]；(c) CH PLIF^[76]；(d) CH₂O PLIF^[78]

发生明显展宽并呈破碎状,符合湍流燃烧模式中破碎反应区的火焰特点。此外,还可以观察到部分区域内的荧光信号与火焰背景辐射强度相当。

利用 CH₂O PLIF 成像火焰结构时,激发激光的波长通常为 355 nm 左右,原因是该波长更便于通过三倍频 1024 nm 激光(由 Nd: YAG 激光器输出)获取,但 CH₂O 在该波长的荧光效率偏低,需要使用较大的激光能量以保证图像的信噪比,一般激光脉冲能量大于 100 mJ。成像发动机凹腔的流向截面时,入射激光能量越高,被凹腔底部金属壁面反射的激光能量也就越多,从而严重干扰荧光信号。为了解决该问题,Rasmussen 等^[78]将相机快门的触发延迟设置为 200 ns,实验中超燃冲压发动机燃烧室入口的来流温度为 430 K、总压为 512 kPa(低温、低压条件下 CH₂O 的荧光寿命较长,如果燃烧室总温、总压较高,CH₂O 荧光寿命会显著缩短,该方法不再适用),对 CH₂O 的成像结果如图 5(d)所示。Micka 等^[75-76]采用荧光效率更高的 352.48 nm 激发波长,降低所需的激光能量,但分析发动机的 CH₂O PLIF 数据时发现,激光片未覆盖的区域也可能出现类似于 CH₂O 荧光的背景信号,这表明图像数据的信噪比偏低。Allison 等^[79]利用 CH₂O PLIF 对发

动机燃烧室展向截面的火焰结构进行成像,激发激光由光学窗口入射到燃烧室,然后经对置的光学窗口离开,规避了金属壁面导致的激光反射问题。为了进一步提高荧光信号强度,还使用了窄频带激光激发技术,采用种子注入技术,将激光的中心波长调整至 355.818 nm,线宽降至约 120 MHz。Gabet 等^[80]的对比研究表明,采用 Nd: YAG 窄频带激光的三倍频激发 CH₂O 获得的荧光强度比宽频带激发增强了 2 倍。

3.2 多组分 PLIF

多组分 PLIF 指在极短时间内(火焰被认为处于冻结状态)对多种组分进行 PLIF 成像,选择的组分一般可标示火焰结构的不同区域,以获取更丰富、完整的火焰结构信息。为了避免不同组分入射激光、荧光信号间的相互影响,需借助时序控制器对不同组分的荧光激发与捕获时间进行精确控制。多组分 PLIF 成像火焰瞬时结构已被广泛用于开放式小型火焰炉的燃烧研究,如图 6 所示。图 6(b)为 Lü

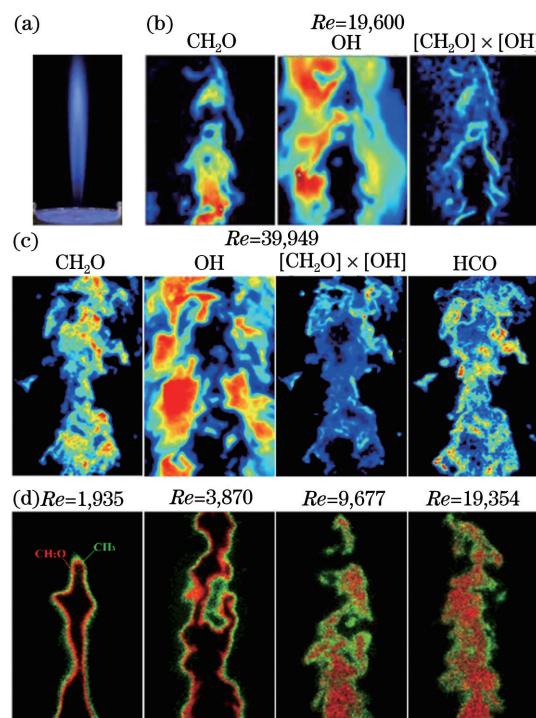

图 6 射流火焰的多组分 PLIF 成像。(a) 射流火焰图像^[27]；(b) CH₂O/OH 同步 PLIF 图像^[27]；(c) CH₂O/OH/HCO 同步 PLIF 图像^[61]；(d) CH₃ PF-LIF 与 CH₂O PLIF 同步测量图像

Fig. 6 Multi-species PLIF imaging of the jet flames. (a) Jet flame image^[27]；(b) simultaneous CH₂O/OH PLIF image^[27]；(c) simultaneous CH₂O/OH/HCO PLIF image^[61]；(d) simultaneous measurement images of the CH₃ PF-LIF and CH₂O PLIF

等^[27]利用 $\text{CH}_2\text{O}/\text{OH}$ 同步 PLIF 对瞬态火焰结构成像的结果, 火焰图像如图 6(a)所示, 其中, Re 为雷诺数; 图 6(c)为 Zhou 等^[61]的 $\text{CH}_2\text{O}/\text{OH}/\text{HCO}$ 同步测量结果; 图 6(d)为国防科技大学用 CH_2O PLIF 与 CH_3 PF-LIF 同步成像的火焰结构。可以发现, 标示火焰预热区的 CH_2O 组分最初仅分布在火焰锋面内侧, 随着湍流强度的增加, 火焰锋面逐渐扭曲、褶皱, CH_2O 最终分散在整个射流区域内, 这表明燃烧模式最终进入分布式反应区, 研究结果与 Zhou 等^[61]的结论相符。 CH_3 的展宽敏感性明显低于 CH_2O , 更靠近火焰释热锋面, 具备在高端流条件下用于成像火焰瞬时结构的潜力。

多组分 PLIF 的另一个重要应用是火焰释热率成像, 火焰释热会明显改变局部温度和压力, 进而影响流场状态, 与许多重要的物理现象有关(如燃烧不稳定性^[66]), 因此一直是燃烧研究的重点。Paul 等^[81]提出利用 OH 和 CH_2O 荧光信号图像的乘积表征释热率分布, 原因是 HCO 可作为释热率分布的标识物, 而 HCO 的浓度与 OH 和 CH_2O 的浓度乘积成正比。对比 OH 和 CH_2O 的乘积图像与 HCO 荧光图像可知, 两者的空间分布结构极其相似。目前关于多组分 PLIF 成像凹腔稳焰超燃冲压发动机燃烧室火焰瞬时结构的研究有 Micka 等^[75-76]的 $\text{CH}_2\text{O}/\text{OH}$ PLIF 工作, 图 7(a)和 7(b)为凹腔稳焰超燃冲压发动机燃烧室展向截面和流向截面同步 $\text{CH}_2\text{O}/\text{OH}$ PLIF 图像。 $\text{CH}_2\text{O}/\text{OH}$ PLIF 同步测量结果揭示了发动机内的部分预混燃烧预热

区和已燃区的瞬时火焰结构, 证明了该火焰结构受凹腔和横向射流引发的流场结构影响。

3.3 火焰结构参数的定量提取

利用 PLIF 成像火焰瞬时结构时, 荧光信号不仅由激光能量、组分浓度决定, 还受局部温度、压力及淬灭作用的影响。荧光信号反映了组分的空间分布结构, 因此 PLIF 图像可用来定量提取火焰的结构参数。OH PLIF 图像的信噪比较高, 不仅可用来提取火焰前锋面位置分布、曲率, 还可用于估算火焰进度变量和火焰面密度^[69,82-83], 如图 8(a)所示。Wang 等^[82-84]基于 OH PLIF 图像定量分析了火焰

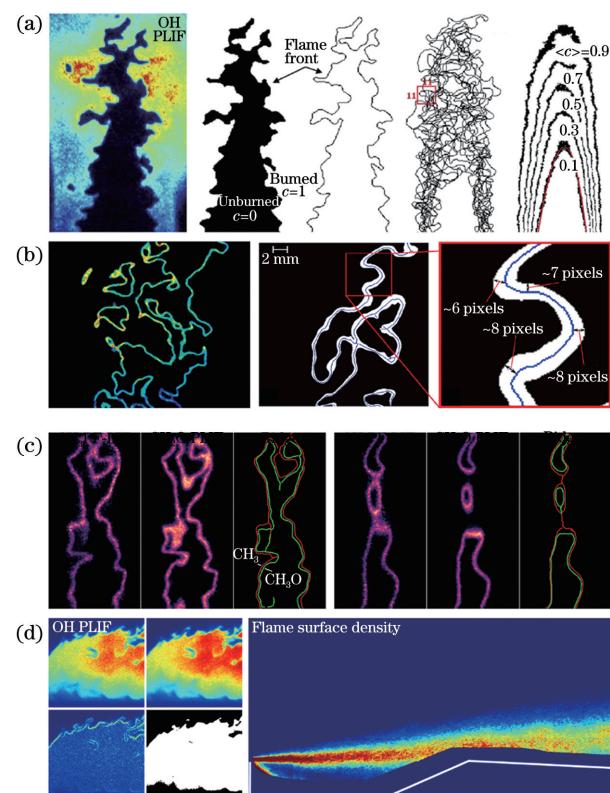

图 8 基于 PLIF 的火焰结构参数定量提取。(a) 基于 OH PLIF 的火焰面、火焰表面密度和进度变量定量提取^[83]; (b) 高湍流火焰的反应区厚度^[86]; (c) CH_3 PF-LIF/ CH_2O PLIF 同步测量图像和脊线提取结果; (d) 基于 OH PLIF 的超燃冲压发动机火焰面密度提取^[70]

结构的特征参数,研究了富氢预混火焰的湍流火焰结构规律。Wu 等^[85]对比了基于 OH PLIF 和其他技术的本生灯火焰层流速度测量方案,发现基于 OH PLIF 的计算结果比实际值约低 5%。Skiba 等^[86]基于分水岭算法提取了 CH 反应层和释热层的厚度,以分析火焰结构随湍流的变化规律,拍摄的 CH PLIF 图像与 CH 组分厚度计算示意图如图 8(b)所示。针对 CH₂O PLIF/CH₃ PF-LIF 同步成像射流火焰结构图像,国防科技大学开展了定量火焰结构提取工作,获得了不同湍流度条件下,不同组分的曲率、厚度、密度、进度变量以及不同组分间距的变化规律。厚度计算结果表明,随着湍流强度的增加,CH₂O 的厚度有明显增加,CH₃ 的厚度则是缓慢增大。图 8(c)为 CH₃ PF-LIF/CH₂O PLIF 同步成像结果及其脊线提取图像。针对发动机的火焰结构定量提取,Geipel 等^[69-70]对发动机内火焰进行高分辨率 OH PLIF 成像,然后提取了燃烧室内火焰倾角、火焰曲率分布、火焰面密度等定量结构参数,结果如图 8(d)所示,并指出这些定量参数可用于超燃冲压发动机的仿真验证。

4 示踪 PLIF 成像组分浓度和温度

在发动机工作过程中,燃料和氧化剂的充分混合是高效燃烧的前提条件。而燃料与氧化剂混合的均匀性、组分浓度和温度分布特性会直接影响点火性能、火焰传播速度及火焰稳定性,进而影响发动机的性能和可靠性^[87-89]。燃烧为发动机的正常工作提供动力,燃烧效率直接决定发动机的推力性能。火

焰温度是研究发动机传热、热负荷及热防护等性能的基础,也是定量评估其燃烧状态、燃烧效率及其推力性能的重要参数^[90-92]。因此,对点火前混合场组分浓度、温度和燃烧过程的火焰温度进行定量测量有助于推动发动机燃烧机理的研究和发动机燃烧室的优化设计。

4.1 燃料分布、浓度和混合流场温度测量

在发动机工作过程中,燃料与氧化剂混合的均匀程度和温度分布特性表征对研究点火和燃烧具有重要意义。传统的燃气分析法在燃气接触取样后可实现燃气组分的定量分析,但这种接触式测量方法受复杂、恶劣发动机实验工况(高速、高湍流)限制,应用范围有限,因此,亟需发展高精度非扰动的激光光学诊断方法^[93-94]。

基于分子示踪的 PLIF 技术主要通过在混合燃气中加入示踪分子(如酮类、苯类、NO)直接获取混合燃气的空间分布信息,通过实验标定和后期数据处理进一步定量获取混合燃气的组分浓度、局部当量比、温度等信息^[89,94-95]。

对于分子示踪 PLIF 技术,常用的示踪粒子可分为有机分子(如甲苯、丙酮,3-戊酮)和无机分子(如 NO)两大类,常见的示踪分子特性参数如表 2 所示。美国斯坦福大学的 Lozano 等^[96-100]、德国杜伊斯堡-埃森大学的 Schulz 等^[101-104]、日本防卫大学的 Kashitani 等^[105]分别研究了不同示踪物质(如丙酮、3-戊酮、甲苯、萘、甲醛)的荧光光谱、寿命与环境温度、压强的关系,为示踪 PLIF 的应用和发展奠定了理论基础。

表 2 常见示踪物质的物理化学参数

Table 2 Physical and chemical parameters of common tracer substances

Parameter	Density / (g·cm ⁻³) 25 °C	Boiling point / °C	Autoignition temperature in air / °C	Excitation wavelength / nm	Fluorescence wavelength / nm	Measurement parameter	Application environment
Acetone ^[101]	0.79	56.1	465—727	225—325	300—500	component concentration/ temperature component	low/high pressure, oxygen-free low/high
3-pentanone ^[99,101]	0.81	102	425—608	248—312	300—500	concentration/ temperature component	pressure, oxygen-free
Toluene ^[100]	0.87	110.6	480—810	~248	260—360	concentration/ temperature	low pressure, oxygen-free
NO ^[95]	1.33×10^{-3}	—151	—	~226	226—290	component concentration	low/high pressure, oxygen-free

研究示踪粒子物理特性和光学特性的同时,人们也将示踪 PLIF 技术应用于混合燃气组分浓度、温度等特性的研究,但受限于混合燃气组分浓度、温度的精确标定,实验主要研究分子示踪 PLIF 的定性表征,定量校准和测量工作研究较少,且目前主要借助示踪物质荧光的强度变化定性描述燃料的分布变化。文献[106-113]基于示踪 PLIF(如丙酮、甲苯、NO)进行了超燃冲压发动机、直喷式汽油发动机、全透明光学发动机等多类发动机燃气-空气混合分布显示实验,结果如图 9 所示。吉雍彬等^[114]利用丙酮 PLIF 技术获取了航空发动机扇段富油-贫油-猝熄(RQL)燃烧室冷态猝熄区燃气的分布结果。俞瑜^[115]用丙酮 PLIF 技术获取了低旋流部分预混燃烧器出口的燃气二维分布图像。孙明波等^[106-107]将丙酮 PLIF 技术用于超燃冲压发动机燃烧室的燃

气混合特性(来流 Mach1.7)研究,获取的丙酮 PLIF 图像与大涡模拟结果基本一致。

在基于示踪 PLIF 技术的混合燃气组分、温度定量测量方面,丙酮、3-戊酮等酮类示踪物质具有毒性小、高饱和蒸气压、压力响应小等优点,被广泛应用于发动机局部当量比、混合燃气浓度、温度等参数的测量^[101];甲苯具有吸收截面大、量子产率高等优点,在发动机测量方面具有较大的应用前景,但该物质易受氧淬灭、压力影响,仅适用于常压无氧环境测量^[100];NO 能反映低温非反应区域的温度场信息,但不适用于燃料分布区域测量(容易和燃料进行反应),且毒性较大^[116-117]。在混合燃气组分定量测量方面,文献[35]、文献[118-121]开展了发动机混合燃气当量比的定量测量实验,结果如图 10 所示。赵纬等^[122-124]也进行了相关研究,Lind 等^[120]基于丙酮 PLIF 技术的 DISI 发动机浓度测量不确定度约为 4.5%。赵纬^[122]利用丙酮 PLIF 和标准定容器(可变压力)标定的形式对天然气发动机喷射射流流场燃气组分浓度分布进行了定量测量。马晓等^[123-124]利用示踪 PLIF 技术(示踪粒子为三乙胺和苯)测量了缸内直喷汽油机内混合气体的浓度分布,获得了燃油轻、中、重三种不同工况下缸内混合气体的浓度分布图像。此外,混合燃气测量结果的标定和校准是示踪 PLIF 技术的关键,目前大多数定量测量结果是通过标准定容器标定和质谱测量标定的方法进行校准,但这两种方法在发动机湍流场(压力、组分分布不均)测量中校准难度较大,因此如何利用高精度的组分定量测量技术进行精准标定仍然是这类示踪技术的难点和热点。

在温度测量方面,由于温度敏感性、饱和蒸汽压等原因,通常使用丙酮、戊酮和甲苯等示踪 PLIF 技术。文献[125-129]基于单线/双线示踪 PLIF 技术开展了发动机混合燃气温度测量实验研究,结果如图 11 所示。Rothamer 等^[99]基于双线 3-戊酮 PLIF 测温技术使内燃机(IC)的温度测量精度达到 2.1%,Willman 等^[128]利用激光诱导光栅光谱单点测温技术(测温精度小于 1%)对单线双示踪物质 PLIF 技术(甲苯和异辛烷)进行校准,获得了 DISI 单缸光学引擎内燃气温度场结果,如图 11(d)所示。张万里等^[130]建立了单线双示踪 PLIF 系统(激发激光的波长为 266 nm,示踪剂为三乙胺和三戊酮),获得了不同示踪剂的荧光强度及其比值随温度、压强和浓度的变化关系,并将标定结果用于发动机缸内混合气体的温度和浓度测量。

4.2 燃烧场火焰温度场测量

发动机内湍流燃烧环境极其复杂,具有高速、高压和高温等特点,且发动机燃烧产生的积碳对激光诊断技术的影响较大(积碳散射、吸收、自发辐射等)^[90-91,131-132],导致大多可用于气体燃烧环境中的激光二维测温技术(如滤波瑞利散射测温技术^[133]、双线OH PLIF测温技术^[134])难以适用。目前获取发动机内部温度及热流场信息的方式仍以数值仿真为主,缺乏实时、准确的二维温度测量手段。

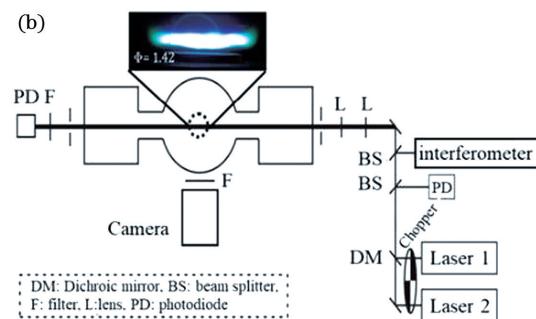

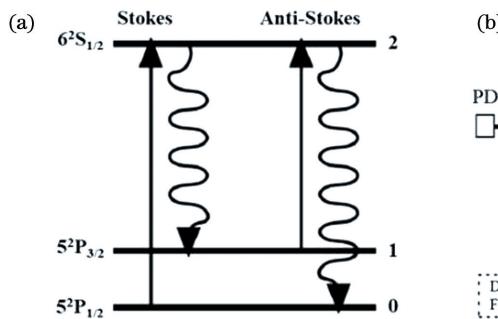

图 12 TLAF 技术示意图。(a)In 原子三能级示意图^[37]; (b)TLAF 测量系统示意图^[39]

Fig. 12 Schematic diagram of the TLAF technique. (a) Three-level diagram of the In atom^[37]; (b) schematic diagram of the TLAF measurement system^[39]

示踪原子的种类、注入、分散是 TLAF 技术研究的重点,目前报道的示踪原子种类主要包括 In、Ga 和 Th 等^[37,39,48],如图 13 和表 3 所示,其中,P 为原子能级。Th 原子有剧毒,在 3000 K 温度以下敏感性较低;Ga 原子在 1000 K 温度以下荧光强度随着温度变化的曲率较大,但在 1000 K 温度以上变化曲率较小,可用于低温(小于 1000 K)的流场测量;In 原子具有温度敏感性较高(500~2800 K)、可见波段激发等特点,因此常用来测量火焰温度^[48]。

目前,基于 In 原子的 TLAF 技术多采用注入 InCl_3 的方法引入 In 原子,由于 InCl_3 需经过火焰面才能分解产生 In,因此,仅能探测高温火焰面后

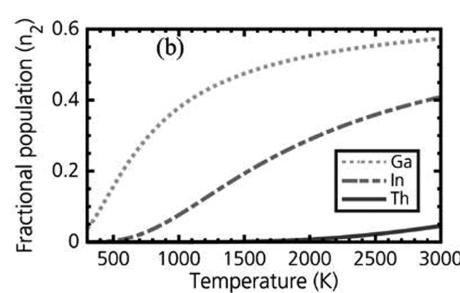

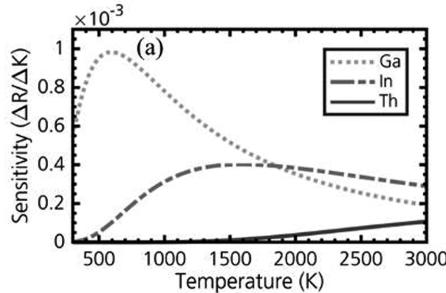

图 13 典型示踪原子的温度特性。(a)TLAF 中不同示踪原子的温度敏感性;(b) 示踪原子的上能级粒子数分布随温度的变化情况^[48]

Fig. 13 Temperature characteristics of typical atomic elements. (a) Temperature sensitivity of the atomic elements for TLAF; (b) variation of the particle number distribution of the upper energy level of the tracer atom with temperature^[48]

双线原子 LIF(TLAF)技术是一种可适用于积碳多、高温、高湍流燃烧环境的二维温度场测量技术。通过在燃料中添加特殊示踪原子(如 In, Ga 和 Th),再采用不同波长的激光激发示踪原子从低能级跃迁到高激发态,高激发态原子向较低能级跃迁产生荧光,根据不同波长荧光的强度分布比值可直接获取燃烧火焰温度场分布^[37,39,135-136],如图 12 所示。该技术具有温度敏感性较好、淬灭效应影响低、时空分辨率高及测温范围宽等优点。

表 3 TLAF 技术中不同示踪原子相关物理常数^[48]

Table 3 Relevant physical constants for the different atoms used for TLAF^[48]

Atomic element	Energy gap / cm ⁻¹	Transitions	Fluorescence wavelength / nm
Ga	826.19	$4\text{P}_{1/2} \rightarrow 5\text{S}_{1/2}$	403
		$4\text{P}_{3/2} \rightarrow 5\text{S}_{1/2}$	417
In	2212.598	$5\text{P}_{1/2} \rightarrow 6\text{S}_{1/2}$	410
		$5\text{P}_{3/2} \rightarrow 6\text{S}_{1/2}$	451
Th	7792.7	$6\text{P}_{1/2} \rightarrow 7\text{S}_{1/2}$	378
		$6\text{P}_{3/2} \rightarrow 7\text{S}_{1/2}$	535

的温度分布;同时 InCl_3 溶液不易挥发,导致荧光测量图像信噪比低^[39,48,137]。Chan 等^[138-139]采用激光烧蚀 In 金属的方法注入 In 原子,可增加示踪原子的空间测量范围,同时可通过调制激光频率和功率

的方式提高注入 In 原子的浓度。Münsterjohann 等^[140-141]采用喷雾热解氧化铟和 TMI 的方式提高注入 In 原子的数量,如图 14 所示,这几种方法均被证实可明显提高 TLAF 图像的信噪比。

TLAF 技术目前主要用于实验室研究阶段,包括线性和非线性 TLAF 技术的研究。针对线性 TLAF 技术,人们主要利用连续激光器和高频光电倍增管开展单点温度测量技术的研究^[142-143],采样频率可达到 10 kHz 以上^[142],测量精度可达到 8 K 左右^[143]。随着高能量脉冲激光器和高量子效率 CCD 相机的发展,线性 TLAF 技术逐渐在二维温度场测量方面崭露头角,文献[37, 39, 140, 144]利用层流和射流火焰开展了二维温度场测量实验研究,结果如图 15 所示。由于激光能量和示踪粒子浓度较低,In 原子荧光探测强度较弱,温度测量结果多为多张荧光图像累加,时间分辨率较低,不适用于湍流燃烧场瞬态测量分析。

为了进一步提高 TLAF 测量信号的信噪比,需要增加注入示踪原子的浓度或提高激光功率。Medwell 等^[145]提出并通过实验验证了非线性 TLAF(NTLAF)是一种很有前景的湍流燃烧场二维温度测量技术,如图 16(a)所示。Chan 等^[146]将 NTLAF 应用于含有碳烟的燃烧火焰测量,证明了

NTLAF 技术具有较强的抗碳烟干扰能力,并发现 NTLAF 荧光信号的主要干扰来源于积碳的先行物多环芳烃(PAH)。Gu 等^[147]利用带宽为 1.2 nm 的窄带滤光片有效滤除了 PAH 对荧光信号的干扰,提高了测温精度。文献[147-149]将 NTLAF 技术应用到层流、扩散燃烧火焰中进行了温度测量实验,结果如图 16(b)~图 16(e)所示,同时采用热电偶或 CARS 技术对温度测量结果进行了校准。其中, Foo 等^[149]获得的瞬态荧光测量图像信噪比可以达到 4.8 以上,温度测量不确定度为 ±139 K。Sun 等^[150]将基于激光模式和能量波动修正算法引入 NTLAF 技术进一步提高了 NTLAF 的测温精度,并基于湍流煤烟火焰开展了温度场测量实验研究,结果如图 16(b)所示,结果表明,NTLAF 技术的相对测量不确定度可以达到 4.1% (200 幅图像的累加),空间分辨率达到 $550 \mu\text{m} \times 550 \mu\text{m}$ 。这些关键技术的研究极大推进了 NTLAF 的发展,但 NTLAF 测温校准过程比较复杂,不仅需要对温度测量结果进行标定,还需对 NTLAF 测量中的多个

(a) Temperature distribution in a laminar premixed flame^[145]; (b) temperature distribution in a non-premixed flame^[150]; (c) temperature distribution in a non-premixed flame^[147]; (d) temperature distribution in a slot burner^[148]; (e) temperature distribution in a non-premixed flame^[149]

系数进行标定,因此如何利用高精度测量技术同步精确地对测量参数进行标定是这类技术实现发动机燃烧火焰温度场测量的关键^[151]。Fang 等^[152]提出了一种基于单参数模型和可调谐二极管激光吸收光谱(TDLAS)技术的校准方法,只需一个系统参数和TDLAS技术获取的平均温度信息就可以实现NTLAF多参数标定,实验测量温度场的不确定度为4.5%,与TDLAS和瑞利散射测温结果的偏差均小于50 K。

综上所述,分子示踪PLIF技术为发动机燃烧流场的实验研究提供了新手段,其测量优势在于混合场浓度和温度、火焰温度等重要参数的高时空分辨瞬态测量,但还需解决示踪分子均匀注入、测量参数精确校准等问题。TLAF技术作为一种新型的燃烧场温度诊断方法,在含有碳烟的燃烧场温度测量中具有很大的优势,有望用于复杂恶劣的发动机实验工况条件。但实现示踪原子的均匀注入、弱荧光信号的高效探测和温度参数的精确标定仍是这类技术应用到发动机测量中的关键问题。

5 基于 PLIF 技术测量燃烧流场速度分布

速度是燃烧流场的重要参数之一,对分析燃烧流场特性、支撑实际燃烧装置的设计能发挥关键作用。分子标记测速(MTV)^[40]技术作为速度测量的前沿技术,具有散播方式简单、随流性好等优势,在高速流场和燃烧场中得到了广泛的应用。

传统的MTV技术通常用激光束分别对示踪分

5.1 基于 NO PLIF 的 APART/ VENOM 测速

以NO作为示踪分子的PLIF测速技术已经得到广泛应用,但产生NO的方式有很多种。空气光

子进行写入和读取,进而实现速度测量,如图17所示。其中, t_0 为初始时刻。写入过程指激光与流场中特定分子相互作用,改变其状态或生成新的分子(如图中的符号T),这一过程标记示踪分子的初始位置。读取过程是对示踪分子的显示过程,通常利用PLIF技术或直接拍摄示踪分子辐射光实现。标记分子的浓度会随时间衰减,其寿命(荧光寿命)需要大于写入和读取的时间间隔 Δt ,是决定测速技术应用范围的重要指标,可利用标记分子的位移d和时间间隔 Δt 获得速度信息。

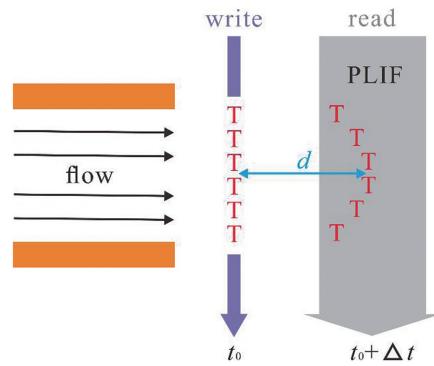

图17 MTV测速技术原理图

Fig. 17 Schematic diagram of the MTV technology

PLIF测速技术是指以PLIF技术作为显示手段获得速度信息的一类测速方法,是MTV技术的关键组成部分。常用的示踪分子包括OH、O₃、NO、Kr和NH等,表4为近年来人们研究的PLIF测速技术及使用的示踪分子等参数,其中, λ_{write} 、 λ_{read} 分别为写入波长、读取波长,M为任意分子,通常称为第三体。

测速技术的参数

解重组示踪测速(APART)技术通过光解空气产生NO,不需要散布其他示踪分子。Dam等^[163]在低速层流条件下,测得气流的速度为(1.11±0.05) m/s。

Laan 等^[164]在3马赫高速自由来流条件下用 APART 技术获得气流的速度为 (630.8 ± 2.7) m/s, 单幅测速精度可达 2%。Bearden 等^[154]提出用波长为 355 nm 的固体激光代替波长为 193 nm 的 ArF 准分子激光, 实验得到的 NO 浓度和 PLIF 图像信噪比较低。APART 技术需要较高的激光能量密度, 且对流场的要求较高。

Orleemann 等^[156]提出的振动激发 NO 测速 (VENOM) 技术利用激光光解 NO_2 产生 NO, 在低压常温条件下, 当空气中 NO_2 散布浓度达 600×10^{-6} 时, 测得 NO 的寿命可达 20 ms。Bathel 等^[157,165-166]在美国航空航天局(NASA)兰利研究中心的风洞中($Ma=10$)实现了单幅高超声速边界层转捩的速度测量, 结果如图 18(a)和图 18(b)所示, 同时修改了 PLIF 系统和风洞模型^[166], 有效提高了图像的信噪比并减少了实验不确定性(约 2 倍), 单幅图像的测量不确定度为 44 m/s。基于双线 LIF 测温^[167]原理, Sánchez-González 等^[168]实现气流的速度和温度测量。ElBaz 等^[155]提出由激光光解 N_2O 产生激发态的 NO, 测速结果如图 18(c)和图 18(d)所示, N_2O 无毒无腐蚀性, 相比 NO_2 更适合开放环境下的测量。直接激发流场中的 NO 也是一

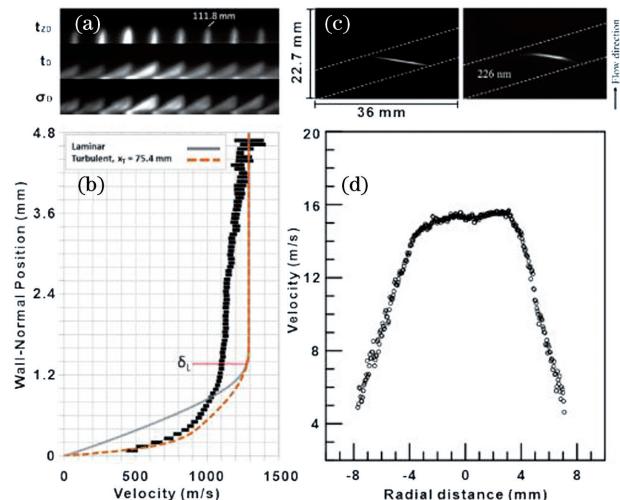

图 18 典型测速剖面图像。(a) 超声速边界层流动 NO PLIF 图像^[157]; (b) 超声速边界层流动速度分布^[157]; (c) 低速射流 NO PLIF 图像^[155]; (d) 低速射流速度分布^[155]

Fig. 18 Typical profile of velocimetry images. (a) NO PLIF images in a supersonic boundary layer^[157]; (b) velocity distribution in a supersonic boundary layer^[157]; (c) NO PLIF images in a low speed jet flow^[155]; (d) velocity distribution in a low speed jet flow^[155]

种可行的标记方法^[169], 但激发态的 NO 易受到 O_2 等分子碰撞淬灭, 使荧光寿命更短, 只适用于超高速流场。Dai 等^[170]在中国空气动力研究与发展中心的高超声速风洞(6~12 马赫)中开展基于 NO PLIF 的速度测量, 平均自由流速度为 3.32 km/s, 不确定度为 5.8%。

NO PLIF 测速技术在测速过程中利用的 NO_x 属于有毒气体, 因此不适用于开放流场尤其是大尺度流场; 且在高温或反应流中 NO_x 和 N_2O 易发生解离或参与化学反应, 导致 PLIF 信噪比降低, 因此这类技术大多应用在常温或低温状态下的非反应流场。

5.2 基于 Kr PLIF 的 KTV 测速

Parziale 等^[158,171]提出的 Kr 分子示踪测速 (KTV) 技术是一种利用 Kr 作为示踪分子的 PLIF 测速技术, 近年来被广泛应用于高速流场测量。KTV 技术的原理是利用波长为 214.7 nm 的激光激发产生亚稳态 Kr, 标记流场初始位置; 一定延迟时间后, 通过 PLIF 技术显示 Kr 的最后位置。在碰撞严重的流场环境下, 亚稳态 Kr 的尺寸为 10 μs 量级。Parziale 等^[158]在非完全膨胀射流中对 KTV 技术的测速能力进行研究, 图 19 为 KTV 测速装置和

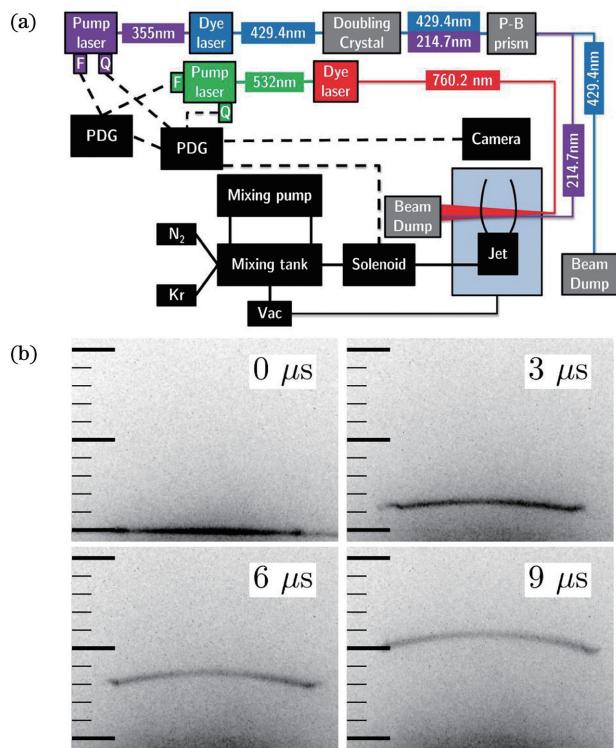

图 19 KTV 技术。(a) KTV 测速装置的示意图; (b) 典型的测速结果^[158]

Fig. 19 KTV technique. (a) Schematic of the KTV speed measurement device; (b) Typical speed measurement results^[158]

典型测速图像,测量结果表明,射流出口速度为707 m/s。

基于KTV技术分别在超声速风洞($Ma = 2.7$)^[172]和高超声速风洞($Ma = 10, Ma = 14$)^[159]实现自由来流的速度测量,结果如图20(a)所示^[159]。

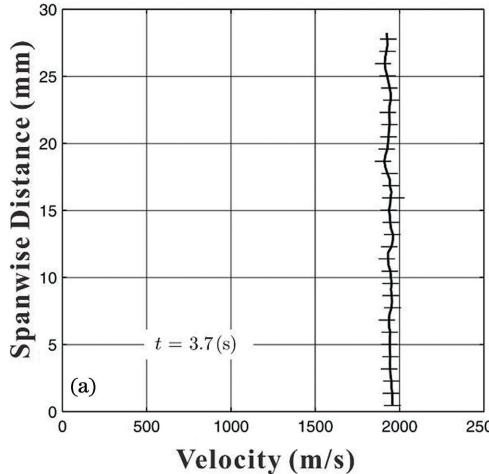

图20 典型平均速度的剖面图像。(a)自由来流^[159];

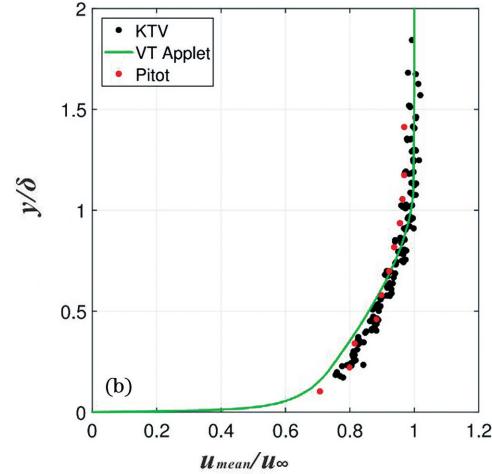

Fig. 20 Profile image of the typical mean velocity. (a) Freestream^[159];

KTV技术的主要优势是处于亚稳态的Kr具有化学惰性,不会与流场中其他物质发生化学反应,目前已实现在高速流场的速度测量。但KTV技术需要额外向流场中散布Kr,稀释气体组分,且分子间的碰撞会提高亚稳态Kr的猝灭速率,尤其在高温燃烧场中碰撞猝灭会更剧烈,使亚稳态Kr的寿命更低,从而降低测速图像的信噪比,因此,KTV技术在高温燃烧场的应用还有待进一步研究。

5.3 基于OH PLIF的HTV测速

羟基分子标记测速(HTV)技术以OH分子作为示踪分子,常利用准分子激光光解流场中的分子产生OH,不需要额外散布其他分子。常温常压下光解产生的OH寿命为几十μm^[177],而高温环境

Mustafa等^[159,173]利用不同激发波长的PLIF实现位置读取,并借助KTV技术研究了激波和湍流边界层的相互作用^[174-176],实现了二维流场速度测量,无量纲化的边界层平均速度剖面如图20(b)所示,其横、纵坐标分别以平均速度和边界层厚度归一化。

(b) 边界层^[174]

对水分子的光解效率和OH浓度有明显增长作用,因此,HTV技术可适用于高温场和燃烧场。

Grady等^[178-179]利用HTV技术在低速非反应流场和燃烧场、火箭尾流场实现速度测量,并与美国空军实验室合作,在超燃冲压发动机^[174,180-181]等高速流场中实现速度测量。在超燃冲压发动机(2马赫)的可压缩流场中,Lahr等^[180,182]利用HTV技术实现了非反应潮湿空气流的速度测量。标记过程采用多线网格式标记,来流速度分别设置为700、300、200 m/s,验证了HTV技术在亚声速和超声速条件下的测速能力,图21(a)为700 m/s时标记的图像。随后,Grady等^[181]分别测量了凹腔台阶后、凹腔后斜坡上和支柱尾流区的HTV标记图像,无

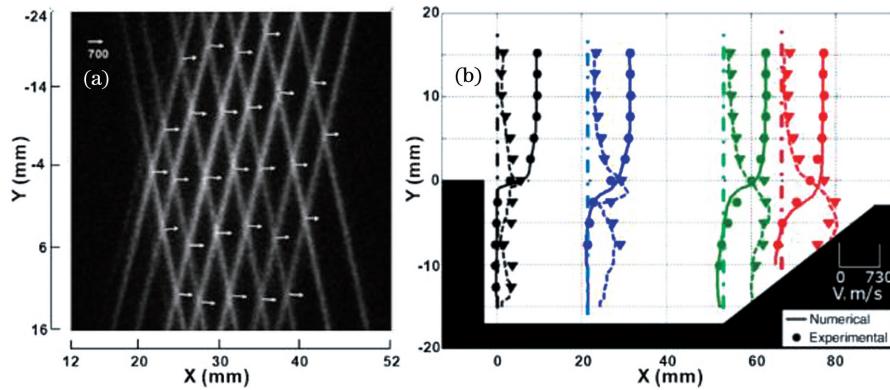

图21 HTV图像。(a)单幅HTV图像^[180];

Fig. 21 HTV images. (a) Single-shot HTV image^[180];

支柱条件下的典型图像如图 21(b)所示,其中点划线为激光标记位置,圆点为平均速度,三角为均方根(RMS)波动。为了实现对速度信息的提取,Ramsey 等^[183]提出一种模板匹配方法对 OH 网格进行跟踪,同时确定了线性位移和旋转位移^[40,179,181]。

Ye 等^[40]在双模态超燃冲压发动机中实现了速度测量,典型测速结果如图 22(a)所示,图 22(a)和图 22(c)为非反应流场,图 22(b)和图 22(d)为反应流场,测速不确定度为 29 m/s。在非反应流场中,标记信号位置清晰,可直接得到主流区和凹

腔内的速度信息;在燃烧流场中,由于强烈的化学反应覆盖了一部分标记信号,只能获得主流区的速度信息,但 OH 作为标志性的燃烧产物,可以显示已燃区的火焰结构。HTV 技术的标记信号在燃烧场中不可避免地会受到燃烧产物等影响,邵珺等^[184-186]针对提取标记信号、去除背景、降低噪声等开展了一系列工作,可有效提高 HTV 图像的信噪比。胡志云等^[187]提出一种有前景的解决方案,由于光解和燃烧产生 OH 的能级不同,选择合适的 OH 激励线可以抑制燃烧产生的 OH 荧光,有利于提高信噪比。

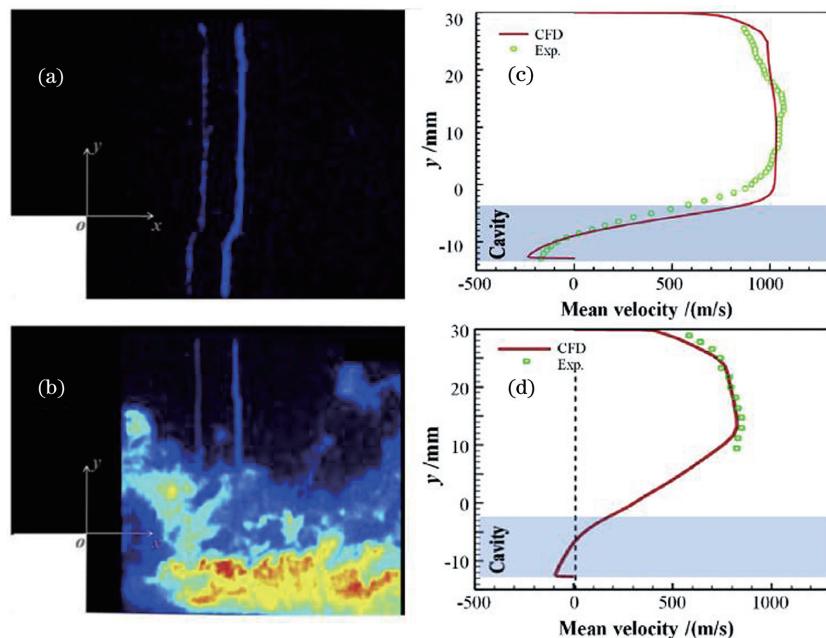

图 22 HTV 图像。(a)无反应流场的 HTV 图像;(b)燃烧流场的 HTV 图像;(c)无反应流场的速度分布;(d)燃烧流场的速度分布^[40]

Fig. 22 HTV images. (a) HTV image of unreacted flow field; (b) HTV image of combustion flow field; (c) velocity distribution of unreacted flow field; (d) velocity distribution of combustion flow field^[40]

HTV 测速技术可直接利用燃烧产物水分子,不需要额外散布示踪分子,且测速范围较宽,可应用于高温场、燃烧场,具有广阔的应用前景。但燃烧反应产生的高浓度 OH 也会干扰 HTV 信号,对信号提取造成困难。在空间上,PLIF 测速技术目前主要实现一维速度测量以及网格式二维速度测量,借助多台相机及空间重构方法也可以实现三维速度测量^[188]。在时间上,ns-PLIF 可测量的时间尺度已满足超声速流动中物理过程的时间尺度,可认为在单个激光脉冲时间内,流场的流动状态不发生改变,而 ps-PLIF 和 fs-PLIF 测量系统可测量的时间尺度比碰撞和反应的时间尺度更小;随着 kHz 和 MHz 脉冲激光系统的应用,每秒可以获得数千幅连续的测

速图像,提供更高时间分辨的高速气体动力学行为信息,有潜力将测速技术的应用范围从 3D 拓展到“3D+t”,不仅可以获得 3D 速度分布,还可以测得不同时刻的速度变化。

6 发展趋势

在基础湍流燃烧和实际发动机燃烧室中,火焰瞬时结构高速脉动,点火、振荡和熄火等动态过程高速演化,使火焰结构具有显著的三维特征,燃烧和流场强烈耦合,传统的~10 Hz 量级、二维和单场(组分场或温度场、流场)测量等 PLIF 技术获得的燃烧流场信息依然有限,未来还需将高速 PLIF、体 LIF(VLIF)、PLIF 技术与其他技术相结合实现多场同

步测量发展。

6.1 高速 PLIF

高速 PLIF 技术的发展主要依赖高重频激光器的研制,高重频脉冲串激光器的问世和发展,使 PLIF 技术的测量频率从 ~ 10 Hz 量级提升到 $10\sim 1000$ kHz 量级,高速 PLIF 技术逐步应用于燃烧诊断中捕捉发动机燃烧室点火时火焰瞬时结构的高速演化过程。

Hammack 等^[189]利用 10 kHz OH PLIF 技术研究了凹腔稳焰超燃冲压发动机燃烧室火焰瞬时结构的动态演化过程,图 23(a)为 2 马赫超声速来流下乙烯燃料燃烧时火焰的贫燃吹熄过程。Miller 等^[41]利用 100 kHz CH_2O PLIF 观测了 2 马赫超声速来流下乙烯燃料的点火和火焰传播过程,如图 23(b)所示。Allison 等^[79]对超燃冲压发动机燃

烧室中的乙烯预混火焰开展了 50 kHz 的 CH_2O PLIF 研究,观测了火焰预热区结构动态演化过程的时间尺度。Carter 等^[64]在甲烷和空气预混火焰中开展 10 kHz CH PLIF 技术研究,利用 $310\sim 320$ nm 范围的 CH (C-X) 激发和探测,以较小的激光能量(0.2 mJ)获得较高的信噪比(~ 20)。目前高速 PLIF 的频率最高可达 1 MHz,Jiang 等^[190]在 3 马赫超声速风洞中实现了 1 MHz NO PLIF 测量,用于观测湍流涡旋结构的高速动态变化过程;Peng 等^[30,191]运用 500 Hz OH PLIF 研究了氢气超声速火焰的振荡频率和点火过程;Yang 等^[192]运用 20 kHz PLIF 和 PIV 测量了旋流火焰的高温释热区域;Wang 等^[193]利用 20 kHz CH_2O PLIF 研究了声激励作用下的旋流火焰振荡特性。

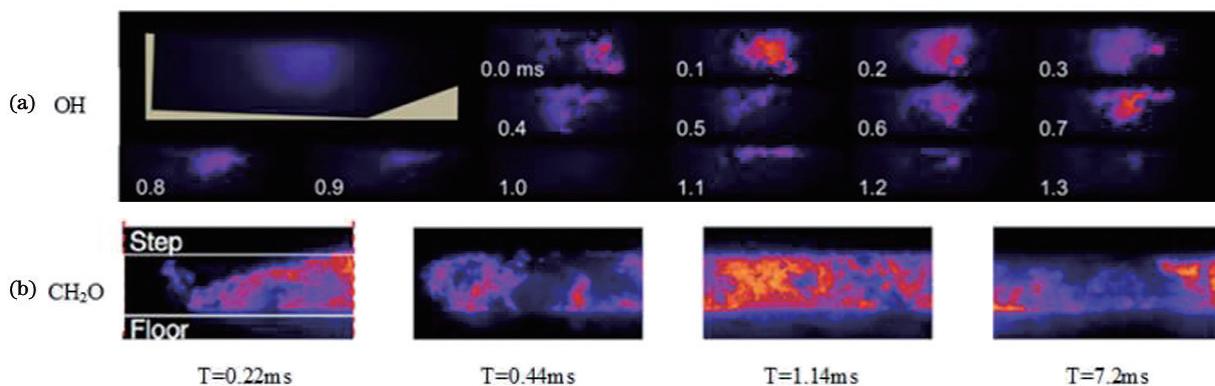

图 23 超燃冲压发动机高速 PLIF 图像。(a) 10 kHz OH PLIF 图像^[189]; (b) 100 kHz CH_2O PLIF 图像^[41]

Fig. 23 High-repetition PLIF images in scramjet engines. (a) 10 kHz OH PLIF images^[189]; (b) 100 kHz CH_2O PLIF images^[41]

高速 PLIF 技术能在 $10\sim 1000$ kHz 范围观测燃烧流场中火焰瞬时结构和流场涡结构的高速动态演化过程,对研究湍流火焰瞬时结构的高速脉动、揭示点火和燃烧振荡过程具有重要意义。高速 PLIF 技术能在较短的时间内获得大量实验数据,便于统计分析,极大提高了实验效率。但高速 PLIF 的重复频率、测量时间和测量范围存在矛盾,随着激光重复频率的提高,激光脉冲能量减少,为了保持图像的信噪比,需要缩小激光光片的测量范围;脉冲串激光器能够实现 ~ 100 kHz 重复频率的输出,单个脉冲串的持续时间为 $1\sim 10$ ms,两个脉冲串之间的时间间隔为 $5\sim 10$ s。优化脉冲串激光器能量和提高稳定性、发展海量 PLIF 图像的分析处理算法、研制新型高重频激光和实现国产化均是未来高速 PLIF 技术发展的主要方向。

6.2 体激光诱导荧光

VLIF 技术能够将 PLIF 技术的二维测量拓宽为三维测量。VLIF 技术目前尚处于探索阶段,主要应用于重构实验室尺度层流和湍流火焰的三维结构^[43]。Wellander 等^[194]通过改变扫描光片的角度改变激光面,用高速相机进行记录并进行图像叠加,对火焰的 OH 基实现了 $3D+t$ 的解析,其实验原理和 OH 分布重构图像如图 24 所示。

Xu 等^[195]利用光学镜片形成体激光,再从五个视角拍摄火焰中的自由基图像,通过空间重构,获得 CH 自由基的三维分布,VLIF 测量方案如图 25(a)所示,其三维火焰重构图像如图 25(b)所示。Ma 等^[43]运用甲烷预混火焰实现了尺寸为 $9.3\text{ mm}\times 9.3\text{ mm}\times 32.7\text{ mm}$ 的 CH 基 VLIF 测量,通过对三维重构火焰的投影图像与单一视角拍摄的图像,测得三维重构火焰的误差在 0.02 mm 以内。

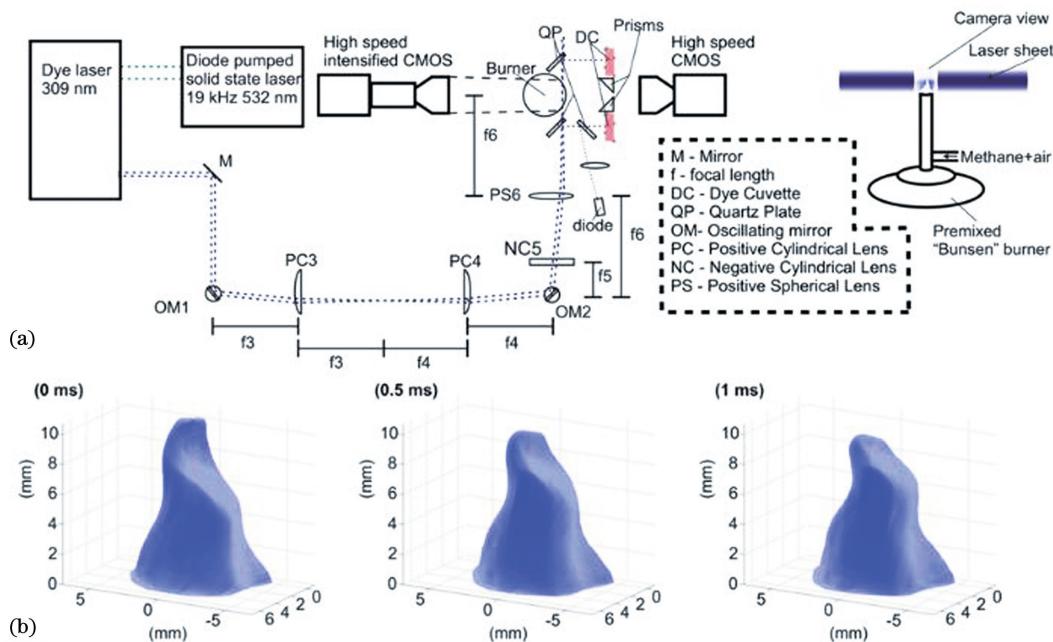

图 24 火焰结构的 3D 重构。(a) 实验示意图; (b) OH 基的 3D 重构^[194]

Fig. 24 3D reconstruction of the flame structure. (a) Experimental schematic diagram; (b) 3D reconstruction of the OH radicals^[194]

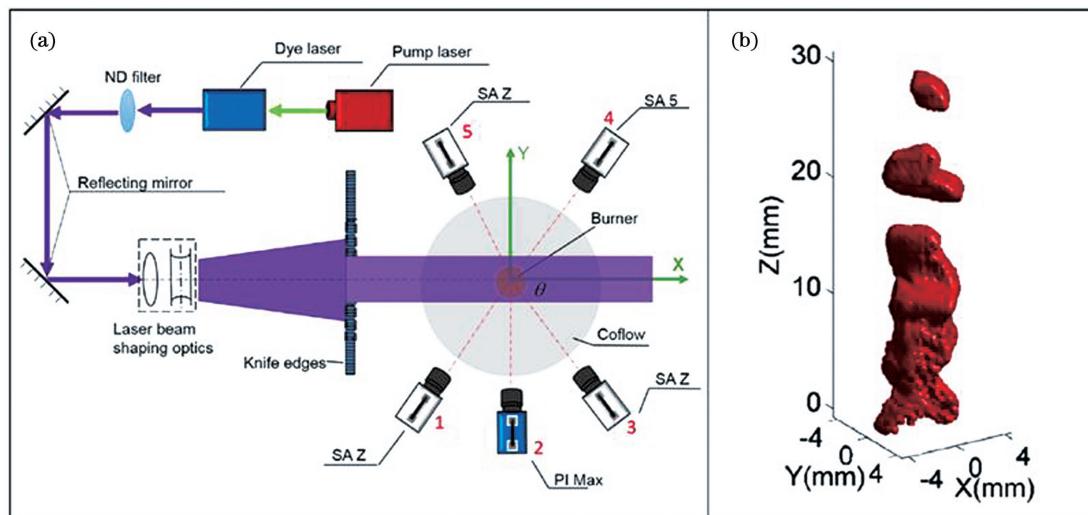

图 25 VLIF 技术。(a) 实验装置示意图;(b) 火焰 CH 基三维重构^[195]

Fig. 25 VLIF technique. (a) Schematic of the experimental setup; (b) three-dimensional reconstruction of the CH radicals in a flame^[195]

Halls 等^[196]对抬升火焰的 OH 基进行了 VLIF 测量。通过四分幅相机耦合 ICCD 相机进行八个平面的 OH 基分布,实现了抬升火焰尺寸为 $40 \text{ mm} \times 35 \text{ mm} \times 55 \text{ mm}$ 的 OH 基 VLIF 测量。

相比 PLIF,VLIF 技术的优点在于能提供火焰的三维信息或 3D+t 解析,未来可能实现多组分的 VLIF 同步测量^[44],但目前 VLIF 技术的测量范围很小,无法实现大范围的立体观测^[197]。VLIF 技术实现难度较大,其光路和相机布置需经过精确计

算^[195]。同时,火焰重构算法的标准不统一,火焰重建时难以精确估计误差^[195]。超声速火焰分布范围广、脉动性强、三维结构复杂,对开展高速 VLIF 诊断具有迫切需求^[198]。但将 VLIF 技术用于观测超燃冲压发动机的三维火焰结构还存在困难,需要广阔的观测视野和复杂的光路布局,全透明光学玻璃燃烧室^[71]未来可能会满足 VLIF 所需的多视角诊断需求。

6.3 多场同步测量

PLIF 技术与粒子成像测速(PIV)、瑞利散射等

非接触激光诊断技术相结合可实现组分场、流场、温度场等多场同步测量^[199]。目前主要应用于 PLIF/PIV 同步测组分和速度场^[180,200]、PLIF/瑞利散射同步测组分和温度场^[201-202]。

PLIF/PIV 同步测量方面, Fugger 等^[46,203]开展了 10 kHz OH/CH₂O PLIF 和 PIV 同步测量, 对火焰的预热区、反应区和速度场进行成像, 测量结果如图 26(a)所示。Boxx 等^[200]对燃气轮机燃烧室中的贫燃预混火焰进行了 kHz 级 OH PLIF 和 PIV 同步测量, 实验结果如图 26(b)所示, 获得了燃烧室速度场和释热率的动态变化过程。Chterev 等^[45]针对旋流燃烧室开展了 5 kHz OH PLIF、煤油 PLIF 和 SPIV 同步测量, 获得了火焰产物区、煤油分布和速

度场的瞬时结构和相对位置分布, 实验结果如图 26(c)所示。Skiba 等^[204]利用多组分 PLIF 和 PIV 对湍流预混火焰的瞬时结构和速度分布进行高频(20 kHz)同步观测, 通过实验证实了湍流涡旋结构可以拓宽火焰前缘。Weinkauff 等^[205]结合 10 kHz 的 SPIV 和丙酮 PLIF 研究了射流火焰的速度场和燃料混合过程。Hammack 等^[206-207]利用 C-X(0,0)谱线实现了 CH PLIF 和 PIV 的同步拍摄。Gao 等^[208]运用 10 kHz PIV 和 CH₂O PLIF 研究了火焰的热声振荡特性。Guo 等^[209-210]采用同步 OH PLIF 和 PIV 技术研究了氢气助燃下的贫燃预混火焰燃烧特性。Fan 等^[211]利用同步 PIV 和煤油 PLIF 技术研究了旋流燃烧室的流场结构和煤油分布特性。

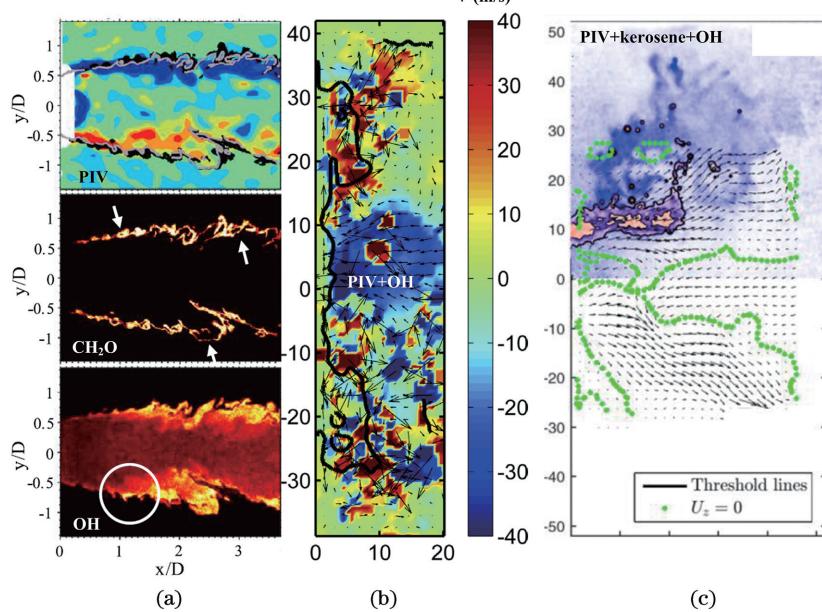

图 26 PLIF/PIV 同步测量图像。(a) 钝体火焰 PIV、CH₂O PLIF 和 OH PLIF 图像^[46]; (b) 抬举火焰 PIV、OH PLIF 图像^[200]; (c) 旋流火焰 PIV、煤油 PLIF、OH PLIF 图像^[45]

Fig. 26 Simultaneous measurement images of PLIF/PIV. (a) PIV and CH₂O/OH PLIF images for the bluff body flame^[46]; (b) PIV and OH PLIF images for the lifted flame^[200]; (c) PIV, kerosene PLIF and OH PLIF images for the swirling flame^[45]

在 PLIF/瑞利散射同步测量方面, Chterev 等^[212]实现了 10 kHz OH/CH₂O PLIF 和瑞利散射的同步测量, 获得了火焰瞬时结构和火焰温度图像, 结果如图 27(a)所示。Skiba 等^[213]用 CH/OH PLIF 和瑞利散射进行同步测温, 结果如图 27(b)所示, 获得了火焰已燃区、反应区和火焰温度的相对位置分布信息。Kong 等^[214]运用 CH₂O/CH PLIF 和瑞利散射研究了等离子体辅助甲烷预混火焰燃烧机制, 结果如图 27(c)所示, 发现了等离子体所产生的高温区域附近 CH₂O 基信号较弱, CH₂O 基主要分

布于低温的燃料分解区。Novoselo 等^[215]结合丙酮 PLIF、CH₂O PLIF 和平面瑞利散射对湍流冷火焰进行了化学动力学分析。Ge 等^[216]将二维瑞利散射获得的主要释热区域与通过 OH PLIF 获得的主要反应区域相结合, 研究了旋流火焰的燃烧特性。

除了 PLIF/PIV 和 PLIF/瑞利散射同步测量外, PLIF 技术还能与其他非接触式光学测量技术相结合实现燃烧流场的多场、多参数测量。PLIF 技术与纹影技术结合使用有助于研究超声速燃烧的动态过程, Do 等^[217]利用纹影技术与 OH PLIF 技术研

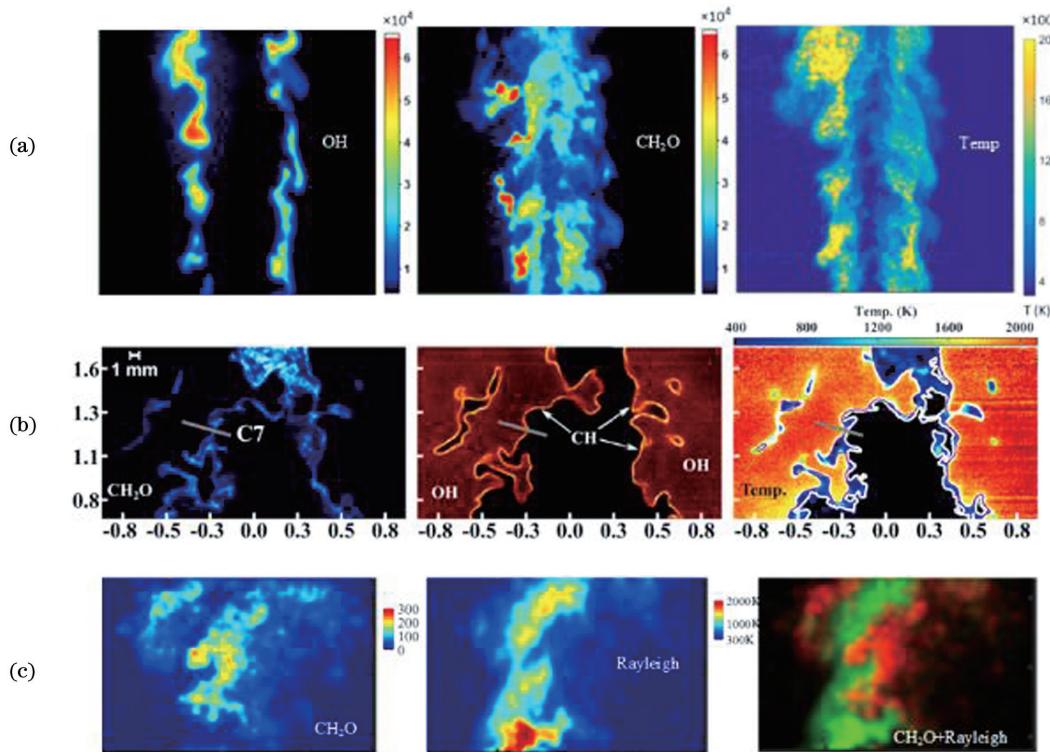

图 27 PLIF 和瑞利散射同步测量图像。(a) OH/CH₂O PLIF 和瑞利散射图像^[212]; (b) CH₂O/OH/CH PLIF 和瑞利散射图像^[213]; (c) CH₂O PLIF 和瑞利散射图像^[214]

Fig. 27 Simultaneous measurement images of PLIF and Rayleigh scattering. (a) OH/CH₂O PLIF and Rayleigh scattering images^[212]; (b) CH₂O/OH/CH PLIF and Rayleigh scattering images^[213]; (c) CH₂O PLIF and Rayleigh scattering images^[214]

究了 ns 脉冲等离子体强化超声速燃烧的效果和机理。PLIF 技术与平面激光诱导炽光(PLII)技术用于研究碳烟的形成,Jain 等^[218]运用 OH PLIF 技术和 PLII 技术研究了 H 原子浓度对于碳烟形成的影响规律。Guiberti 等^[219]实现了 CH₂O PLIF、OH PLIF、CH₄ 拉曼散射和 PIV 的同步测量,对抬升射流火焰的未燃区、已燃区、当量比和速度场进行了同步测量。Liu 等^[220]利用 PLIF 技术和激光诱导击穿光谱(LIBS)技术,研究了生物质燃料燃烧过程中的钾释放过程和影响因素。

多场同步测量有助于将同时获得的组分场、流场和温度场等综合信息进行对比研究,但实验系统复杂,时序同步、空间合束等操作难度大,多束激光的使用可能带来额外的杂散光,降低图像的信噪比。受限于光路调节的难度和实验系统的复杂性,多场同步测量主要应用于实验室尺度基础层流和湍流火焰的诊断,随着激光诊断技术的不断发展和完善,多场同步测量技术有望应用于发动机燃烧流场的诊断,将组分场与速度场、温度场等其他物理量进行同时测量,以获得发动机燃烧室的多参数综合信息,为

发动机燃烧室的优化设计提供支撑。

PLIF 技术可应用于固体颗粒或碳烟颗粒的燃烧诊断中。Park 等^[221]运用 Kr PLIF、PIV 和 LII 同步测量了湍流非预混火焰中碳烟颗粒的耗散率和体积分数,碳烟颗粒的散射光可被窄带滤波片过滤。Köser 等^[222]运用 PLIF 对比自发辐射研究了单个煤颗粒的燃烧过程,相比自发辐射,OH PLIF 更有利于研究煤颗粒内部的燃烧过程。Balusamy 等^[223]运用米散射和 OH PLIF 技术研究了煤颗粒的燃烧过程。煤颗粒和燃烧中碳烟颗粒的米散射会对 PLIF 信号造成干扰,使用窄带滤波片并调整相机延迟可以有效降低信号干扰。

PLIF 技术还可用于诊断液态燃料的燃烧,Wang 等^[224]针对超声速火焰实现了煤油 PLIF 和 OH PLIF 的同步测量,在测量 OH PLIF 时激光诱导煤油和其他大分子会产生 PAH 信号。Malbois 等^[225]利用 10 kHz OH PLIF 和 PIV 研究了煤油旋流火焰的 OH 基分布和速度场,拍摄 OH PLIF 时发现燃烧室入口附近的大尺寸煤油液滴具有较强的米散射。激光诱导液态燃料产生的荧光可能会干扰

目标粒子的荧光,且激光穿过液滴时会发生散射,导致激光在平面上分布不均匀,对定量分析产生影响,因此需要根据激光强度分布对荧光信号进行校正^[224]。

7 结论与展望

LIF技术作为研究燃烧的重要测量手段,具有非扰动、实时原位测量、组分选择性强、灵敏度好、时空分辨率高等优势,多组分PLIF技术、示踪PLIF技术、基于PLIF的MTV技术已经广泛应用于燃烧诊断中测量火焰瞬时结构、组分浓度、温度和流场速度等重要特征参数。

PLIF技术能够通过成像燃烧过程中CH₂O、OH和CH等重要组分的二维分布,实现对发动机燃烧室火焰预热区、已燃区和反应区瞬时结构的高时空分辨可视化;通过加入丙酮、甲苯等示踪物质显示发动机混合场组分浓度和温度等重要信息,TLAF能测量火焰温度的二维分布;MTV技术利用PLIF实现读的功能,从而测量冷流场和燃烧场中的流速分布,测量范围从低速拓宽到高超声速。尽管LIF技术在燃烧诊断中已经取得重要研究进展,但存在着重复频率低(~ 10 Hz)、维度少(2D)、单场测量等问题。

随着高能高重频脉冲激光器的发展,高速PLIF技术(10~1000 kHz)逐步应用于燃烧诊断中测量点熄火、燃烧振荡等过程中火焰瞬时结构的动态演化。VLIF技术在开敞空间的火焰炉中已经被演示验证,能够成像火焰的三维结构,且与高速激光器结合能实现4D(3D+t)测量,未来有望应用于成像发动机燃烧室火焰三维瞬时结构的高速演化过程。PLIF技术与PIV、瑞利散射等技术同步使用,能实现组分场/流场/温度场的多场、多参数同步可视化,有助于进一步揭示燃烧与湍流相互作用机理。VLIF技术和多场多参数同步诊断技术目前主要应用于基础燃烧诊断,但还需要解决复杂光路调节和光学视窗设计、燃烧室壁面杂散光滤除、信噪比优化等问题。

仅依靠LIF技术获得的发动机燃烧流场信息依然有限,PLIF测量结果需要更好地结合理论模型和数值模拟结果,才能进一步揭示发动机混合、流动、燃烧的特性和机理,为发动机燃烧室的优化设计奠定基础,为提高发动机燃烧效率和推力性能提供支撑。

Research Progress of Laser-Induced Fluorescence Technology in Combustion Diagnostics

Zhu Jiajian*, Wan Minggang, Wu Ge, Yan Bo, Tian Yifu, Feng Rong, Sun Mingbo

Science and Technology on Scramjet Laboratory, College of Aerospace Science and Engineering, National University of Defense Technology, Changsha, Hunan 410073, China

Abstract

Significance Laser-induced fluorescence (LIF) can be used to perform non-intrusive, in-situ, and temporally and spatially resolved measurements of combustion characteristics with strong species selectivity and good sensitivity. This paper reviews research progress in the development and application of multi-species planar LIF (PLIF), tracer PLIF and PLIF-based velocimetry in combustion diagnostics to measure instantaneous flame structure, fuel concentration, temperature, and velocity. This work also discusses the typical examples, characteristics, and challenges of conducting PLIF in fundamental combustion diagnostics and practical engine measurements. The technological trends about high-repetition PLIF, volumetric LIF (VLIF), and simultaneous multi-parameter measurements are also presented.

Progress The PLIF can visualize the two-dimensional distributions of multi-species generated during the combustion process and show the instantaneous flame structure. The formaldehyde (CH_2O) can be used as an indicator of the flame preheating zone, and OH radicals can be regarded as a flame marker of the product zone. Simultaneous PLIF measurements of the CH_2O and OH can obtain the heat release zone of a premixed turbulent flame shown in Fig.6(a). Fig.6(b) and Fig.6(c) show CH_2O and OH PLIF images that are acquired simultaneously as well as the distributions of the heat release zone that are obtained by the pixel-by-pixel product of OH and CH_2O . CH

radicals in flames are usually employed to indicate the flame reaction zone. The CH radicals are difficult to be measured by PLIF due to their relatively low concentration in flames. The signal-to-noise ratio of the CH PLIF can be significantly improved by using a high-energy tunable Alexandrite laser at ~ 387 nm and the C-X excitation at ~ 314 nm. The distributed reaction zone can be identified in a high-speed jet flame by broadening CH distributions that can be observed by the CH-PLIF. The HCO and CH_3 radicals that indicate instantaneous flame structure can be measured by single-shot HCO PLIF and photofragmentation LIF, and the two-dimensional distributions of HCO and CH_3 are shown in Fig. 6(c) and Fig. 6(d), respectively. The OH, CH, and CH_2O PLIF can be used to obtain instantaneous flame structures in a cavity-based scramjet combustor, which helps to better understand the flameholding modes and mechanism in a supersonic flow. Feature extraction of the turbulent flame front, the flame surface density, the progressive variable, and the ridge can be achieved from the PLIF images, which gives quantitative information of the flame structure and sheds light on interactions between combustion and turbulence.

The tracer PLIF can measure fuel concentration, equivalence ratio, and temperature during the mixing process by adding fluorescent tracers into small-scale burners or practical combustion systems. Characteristics of the frequently used tracer molecules are described, such as acetone, 3-Pentanone, toluene, and NO. Typical applications of the tracer PLIF in showing the fuel distribution, equivalence ratio, and temperature distribution during the mixing process of different engines are introduced. The two-line atomic fluorescence (TLAF) can be used to indicate the two-dimensional distribution of the flame temperature by seeding atomic elements into a flame. Temperature characteristics of typical atomic elements (e.g. gallium, indium, and thallium) are compared, and different seeding methods for the indium atom are introduced. Linear and nonlinear TLAF methods with the indium atom seeding can be used to show two-dimensional distributions of the flame temperature. Nonlinear TLAF is a promising technique for two-dimensional temperature measurements in a harsh environment with an acceptable signal-to-noise ratio. The challenges of conducting the tracer PLIF in quantitative measurements are presented. Accurate calibrations of the fluorescence intensity in different conditions of temperature and pressure play a key role in the quantitative measurements of the tracer PLIF and TLAF techniques.

The PLIF techniques can be used in molecular tagging velocimetry (MTV) to non-intrusively measure the velocity distribution of the flow field. In the MTV technique, a ‘write’ laser pulse is employed to generate flow tracer (e.g. NO, Kr and OH) with a relatively long-lifetime fluorescence through the process of photodissociation, excitation, or photochemical reaction, and then a ‘read’ laser pulse is used to tag the location displacement and the delay time of the tracers. The NO PLIF, Kr PLIF, and OH PLIF are usually adopted during the ‘read’ process of the MTV technique. The air photolysis and recombination tracking (APART)/vibrationally excited NO monitoring (VENOM), krypton tagging velocimetry (KTV), and hydroxyl tagging velocimetry (HTV) have been widely used in measuring the velocity distribution in a cold or reacting flow ranging from low to hypersonic velocity.

Conclusion and Prospect LIF is a non-intrusive and in-situ technique, which can be used to accurately measure instantaneous flame structure, fuel concentration, temperature, and velocity of flames and engine combustion. The repetition rate and measurement dimension of LIF techniques are required to be further improved. With the development of high-energy and high-repetition pulsed lasers, the high-speed PLIF technology (10 – 1000 kHz) can show the dynamic evolution of instantaneous flame structure during the process of flame ignition, flameout, and combustion oscillation. The VLIF technology can be employed to demonstrate the three-dimensional structure of the flame and realize four-dimensional (three-dimensional + t) measurements in combination with a high-speed laser. The PLIF can be synchronized with PIV, Rayleigh scattering, and other techniques to realize the simultaneous visualization of instantaneous flame structure, flow velocity, and flame temperature, which helps to further reveal the interaction mechanism of combustion and turbulence.

The applications of the PLIF techniques in practical engines need to solve many problems, such as complex optical path adjustment and optical window design, stray light suppression, and signal-to-noise ratio optimization. The combustion information obtained by the PLIF techniques is still limited. The PLIF techniques need to be combined with other measurement methods, theoretical models, and numerical simulations to better understand the characteristics and mechanisms of combustion.
