Abstract: A fabrication method of the multi-wavelength fiber grating (FBG) was introduced. Using the scan exposure method, the multi-wavelength FBG can be successfully manufactured through applying different tensile forces during the multiple exposures process on the same fiber. Experiment results show that the position and the overlap of different sub FBGs will greatly affect the spectrum of every sub FBG. The spectrum of each sub FBG will be affected by short wave oscillation unless the lengths and positions of all sub FBGs are fully overlapped. For hydrogen loaded fiber, the wavelength and reflectivity of the n th level FBG will increase as the $(n+1)$ th level FBG is written. But for germanium doped photosensitive fiber, multiple exposure will increase the wavelength of previous sub FBGs while decrease the reflectivity of all sub FBGs. Through well distributing exposure intensity of every sub FBGs, a four-wavelength FBG with same sub FBG's spectrum was fabricated on a hydrogen loaded single mode fiber.

1. Introduction

The fiber Bragg grating (FBG) is an important optical filter, in the study of more than 20 years, various FBGs and fabrication methods have been introduced which play a great role in the fiber lasers, optical fiber sensors, and communication technology [1, 2]. In addition to some special structure FBGs just like long period FBG [3], blazed FBG [4], sampled FBG [5], and multimode FBG [6] having a spectrum with multiply reflection band, the spectra of ordinary FBGs are all the basic single wavelength. Although several FBGs series-connected on a single fiber can realize multi-wavelength distribution, but

the structure is not convenient to use for the long size. It is found that, in experiments, the FBG will not be bleached when exposed again on the same section of the fiber, but form multi reflection band corresponding to the force tensing on the fiber. In this paper, a new method of fabrication of multi-wavelength FBG in a fiber is introduced using the grating wavelength tension control technology. A four-wavelength FBG with a consistent spectrum shape was fabricated by multi exposures with different tensions on the fiber.

2. Experiment

The scanning exposure method of FBG

fabrication based on the phase mask is considered as most flexible and reliable in various methods. It is not only easy to control the basic parameters of the FBG such as the wavelength, reflectivity, and length, but also convenient for refractive index modulation to achieve apodization, being chirped and phase-shifted on the FBG [7]. The fabrication system of FBG is illustrated in Fig. 1. The FBG is fabricated by UV scanning espousing by moving UV source or the piece of fiber. The wavelength range is determined by the period of the phase mask, while the exact wavelength is determined by the force pulled on the fiber when exposing, and the bigger the force is, the shorter the wavelength is [8].

Fig. 1 Fabrication system of FBGs.

Hydrogen loading makes fiber high photosensitive, which ensures that expected results of refractive index modulation can be very well showed in the grating spectrum. The phase mask method has undemanding coherence of the ultraviolet (UV) light source, which allows us to use excimer lasing at 248 nm. The FBG with a length of 10 mm was fabricated by setting the pulse energy of excimer laser as 10 mJ and the scanning velocity as 0.1 mm/s during each exposure. Firstly, the FBG with a central wavelength of 1551.33 nm and reflectivity of -31 dB was fabricated under exposure at a frequency of 120 Hz, while the tension was maintained at 50 g by the use of fiber holder and strain gauge during exposure, as shown in Fig. 2(a). Then, the tension imposed on fiber was adjusted to be 100 g, and the second scanning exposure at the

same frequency of 120 Hz brought dual central wavelength to the FBG, which had a central wavelength of 1550.64 nm and a reflectivity of -30.6 dB. Meantime, the stop-band of the first layer of the grating moved to 1551.54 nm, and its reflectivity changed into -36 dB, with an increase in the central wavelength and reflectivity simultaneously as shown in Fig. 2(b).

Fig. 2 Spectra change of the FBG: (a) first exposure at 50 g tensile force and (b) second exposure at 100 g tensile force.

If the positions of the two layers of the grating are staggered by 2 mm, i.e. the total grating length is 12 mm, and their overlapping part is 8 mm, the spectra of the two gratings will both lose their symmetry as single-wavelength, short wave oscillation issue emerges, and the reflection is weaker than that of the single grating, as shown in Fig. 3.

Based on the above experimental results, the four-wavelength FBG was designed and fabricated after many calibrating tests. Each layer of the sub-grating was fabricated on hydrogen loaded sensitive enhanced single-mode fiber with the UV pulse energy of 10 mJ and scanning velocity of 0.1 mm/s, with the exposure frequency and fiber tension as shown in Table 1. The four-wavelength FBG had a uniform wavelength interval within 0.05 nm error and a reflection of the sub-grating of around -23 dB with the good consistency

as shown in Fig. 4.

Fig. 3 Spectra of the double-wavelength FBG with 2 mm dislocation: (a) first exposure at 50 g tensile force and (b) second exposure at 100 g tensile force.

Table 1 Fabrication conditions of every sub-FBG

	1st level	2nd level	3rd level	4th level
Exposure frequency	100 Hz	110 Hz	120 Hz	130 Hz
Tensile force	50 g	100 g	150 g	200 g

And Nufern GF1 germanium-doped photosensitive fiber was also used to repeat the fabrication as above. The results reveal that the multi-wavelength FBG can also be written on germanium-doped fiber. However, the reflectivity of all the sub-gratings decrease significantly with more layers of the grating no matter how we change the exposure, as shown in Fig. 5.

3. Discussion

As we all known, the Bragg wavelength and reflection of the normal FBG can be described by $\lambda_B = 2(n_0 + \Delta n_{\text{eff}})A_g$ and $R = \tanh^2\left(\frac{\pi}{\lambda_B} \nu \Delta n L\right)$ [9, 10], while n_0 is the refractive index of the core, Δn_{eff} is an average increase induced by UV exposure, Δn is the amplitude of refractive index modulation, ν is the fringe visibility of refractive index modulation, and A_g is the grating period. If the larger tension is applied on the fiber during exposure, the smaller A_g is obtained after the tension is released, therefore the shorter wavelength FBG is got.

The wavelength of sub-gratings formed first under multiple exposure increases with larger Δn_{eff} under accumulation of local exposure no matter what kind of exposure technology or photosensitive fiber is used. Due to the lower coherence of excimer laser, the ν value of the FBG is so small that the high reflection depends on an increase in Δn under strong exposure [11]. For hydrogen loaded photosensitive fiber, although the ν value of each layer of the grating is getting weaker during interaction, the relative change is finite, and Δn of each layer of the grating

increases during intercoupling. Hence, the reflection of the sub-grating increases. While Δn of germanium doped photosensitive fiber is nearly one magnitude lower than that of hydrogen loaded photosensitive fiber under the same exposure, attributing to its limited photosensitivity [12], the weakening of ν is more obvious than an increase in Δn , which results in lower reflection.

The responses of the fabricated four-wavelength FBG to temperature and strain were tested individually as shown in Figs. 6 and 7, where perfectly consistent performances were obtained due to the same material property of the four sub-gratings. Despite no superiority to the single wavelength applied in fiber sensing based on the wavelength demodulation technology, this could be quite valuable for the fiber laser and fiber filter [13–15].

4. Conclusions

Based on the scanning exposure method by the

use of the excimer laser and phase mask, a novel multiple exposure method was realized to fabricate the multiple-wavelength FBG at the same position. The multiple-wavelength FBG is easier to be fabricated on hydrogen loaded photosensitive fiber than on germanium doped photosensitive fiber. The FBG length and position should be kept consistent to keep the spectrum of the sub-grating from short wavelength oscillation. The sub-gratings of the multiple-wavelength FBG have the same wavelength to temperature and strain response. The multiple-wavelength FBGs with different wavelength intervals can be obtained by the FBG wavelength and tension control technology. It will play a role in the fiber laser and fiber filter, etc.
