With great achievements in efficiency, stability, and large-scale preparation of perovskite solar cells (PSCs), the commercialization of PSC is ongoing, but there is still an issue on lead toxicity. Although lead content in the device is low, the water solubility of lead salts leads to potential environmental pollution. At present, the non-lead perovskites studied include: divalent metal perovskite (e.g., Sn<sup>2+</sup>, Ge<sup>2+</sup>, Cu<sup>2+</sup>), trivalent metal perovskite (e.g., Bi<sup>3+</sup>, Sb<sup>3+</sup>, In<sup>3+</sup>), tetravalent metal double perovskite (e.g., Sn<sup>4+</sup>, Pd<sup>4+</sup>, Ti<sup>4+</sup>, Pt<sup>4+</sup>) and monovalent mixed double perovskite (e.g., Ag<sup>+</sup> and Bi<sup>3+</sup>, Ag<sup>+</sup> and In<sup>3+</sup>, Ag<sup>+</sup> and Sb<sup>3+</sup>). Their properties are summarized in Table 1. Since the first report on non-lead double perovskite Cs<sub>2</sub>AgBiBr<sub>6</sub> in 2016<sup>[1]</sup>, this material has caused extensive research in optoelectronic devices because of its long carrier lifetime<sup>[1]</sup> and good stability<sup>[2]</sup>. However, owing to its wide and indirect bandgap ( $E_g$ ) (~2.0 eV), its light absorption range is narrow, which limits its application in photovoltaics. At present, the power conversion efficiency (PCE) of Cs<sub>2</sub>AgBiBr<sub>6</sub> device is ~3%<sup>[3]</sup>. To enhance PCE, the  $E_g$  needs to be narrowed. The efforts in this area focus on adjusting chemical composition and physical structure (Fig. 1) to tune  $E_g$ .

A common attempt to tune the  $E_g$  of double perovskite is to adjust the chemical composition of compound A<sub>2</sub>B(II)B(III)X<sub>6</sub>.

**A-site.** Doping alkali metal ions like Rb<sup>+</sup>, K<sup>+</sup>, and Na<sup>+</sup> made little effect on  $E_g$ <sup>[4]</sup>. Chen *et al.*<sup>[5]</sup> introduced Rb<sup>+</sup> into Cs<sub>2</sub>AgBiBr<sub>6</sub> to form (Cs<sub>1-x</sub>Rb<sub>x</sub>)<sub>2</sub>AgBiBr<sub>6</sub> and effectively passivated the defects of double perovskite, thus increasing PCE to 1.5%. But this doping could not significantly change the  $E_g$ . When doping A-site to change the dimension of perovskite from 3D to 2D, the  $E_g$  and electronic structure can be tuned. In 2019, Mitzi *et al.*<sup>[6]</sup> reported that a stable 2D double perovskite [AE2T]<sub>2</sub>AgBiI<sub>8</sub> was formed by using multifunctional organic molecules with a direct  $E_g$  of 2.01 eV.

**X-site.** For lead-based perovskites, the  $E_g$  decreases with the increasing of halogen atom radius, and similar results are also observed in double perovskites. The introduction of Cl<sup>-</sup> can greatly increase  $E_g$ , while I<sup>-</sup> doping can significantly reduce  $E_g$ , which is 2.77 eV (X = Cl), 1.95 eV (X = Br), and 1.75 eV (X = I) for Cs<sub>2</sub>AgBiX<sub>6</sub><sup>[7]</sup>. When X site is I, the stability for double perovskite decreases. It is difficult to prepare

Cs<sub>2</sub>AgBiI<sub>6</sub> experimentally, because the formation energy of Cs<sub>3</sub>Bi<sub>2</sub>I<sub>9</sub> is lower. As reported by Ma *et al.*<sup>[8]</sup>, the  $E_g$  of Cs<sub>2</sub>NaBiI<sub>6</sub> was relatively narrow (1.66 eV), but it can easily decompose into Cs<sub>3</sub>Bi<sub>2</sub>I<sub>9</sub>, yielding a 0.42% PCE.

**B-site.** The structure of double perovskite consists of B(II)X<sub>6</sub> and B(III)X<sub>6</sub> with alternating octahedrons connected by vertices. Substituting B-site elements can tune  $E_g$ . Karunadasa *et al.*<sup>[9]</sup> found that doping low content of toxic TI (TI<sup>+</sup>, TI<sup>3+</sup>) into Cs<sub>2</sub>AgBiBr<sub>6</sub> to form Cs<sub>2</sub>(Ag<sub>1-a</sub>Bi<sub>1-b</sub>)TI<sub>x</sub>Br<sub>6</sub> (0.003 < x = a + b < 0.075) can significantly reduce its  $E_g$  to 1.40 eV for Cs<sub>2</sub>(Ag<sub>1-a</sub>Bi<sub>1-b</sub>)TI<sub>0.075</sub>Br<sub>6</sub>. Replacing Ag<sup>+</sup> and Bi<sup>3+</sup> by TI<sup>+</sup>/TI<sup>3+</sup> yielded defects, leading to band-edge reconstruction. Using unstable Sn<sup>2+</sup> (can be oxidized to Sn<sup>4+</sup>) to replace both Ag<sup>+</sup> and Bi<sup>3+</sup> can also reduce  $E_g$  to 1.71 eV (indirect) and 1.48 eV (direct)<sup>[10]</sup>. These results indicate that the band-edge reconstruction caused by the lattice distortion due to B-site ion doping can tune the  $E_g$  of double perovskite. Mitzi *et al.*<sup>[11]</sup> reported that the use of trivalent metal In<sup>3+</sup> or Sb<sup>3+</sup> can also significantly tune  $E_g$ , which could be increased to 2.4 eV by replacing 75% of Bi<sup>3+</sup> with In<sup>3+</sup>. While replacing 37.5% Bi<sup>3+</sup> with Sb<sup>3+</sup> could reduce  $E_g$  to 1.86 eV. When using In<sup>+</sup> to replace Ag<sup>+</sup>, it was predicted that the  $E_g$  of Cs<sub>2</sub>InBiCl<sub>6</sub> (1.02 eV) and Cs<sub>2</sub>InSbCl<sub>6</sub> (0.91 eV) would be very suitable for photovoltaics<sup>[12]</sup>. However, In<sup>+</sup> is extremely unstable and can be easily oxidized into In<sup>3+</sup><sup>[13]</sup>.

When using Cu<sup>+</sup>/Cu<sup>2+</sup> to replace part of Ag<sup>+</sup> in Cs<sub>2</sub>AgBiBr<sub>6</sub>, there is no obvious effect on  $E_g$ <sup>[14]</sup>. Cu<sup>+</sup> (ionic radius 77 pm, hereafter omit) and Cu<sup>2+</sup> (73 pm) are much smaller than Ag<sup>+</sup> (115 pm). They can cause lattice defects, and the absorption tail extends from 610 to 860 nm. This was due to the absorption of the defect intermediate state. Similarly, Fe<sup>3+</sup> (65 pm) was used to replace part of Bi<sup>3+</sup> (103 pm)<sup>[15]</sup>. Since the size of Fe<sup>3+</sup> is quite different from Bi<sup>3+</sup>, it can easily cause lattice distortion and defects. The lattice constant was reduced from 11.27 to 11.25 Å, and Cs<sub>2</sub>AgBi<sub>0.886</sub>Fe<sub>0.114</sub>Br<sub>6</sub> was obtained as a black crystal. Though  $E_g$  did not change obviously, the light absorption was greatly increased by defects. Recently, Gao *et al.*<sup>[16]</sup> demonstrated that Fe<sup>3+</sup> could replace diamagnetic In<sup>3+</sup> to yield Cs<sub>2</sub>AgIn<sub>1-x</sub>Fe<sub>x</sub>Cl<sub>6</sub> and form [FeCl<sub>6</sub>]<sup>3-</sup>-[AgCl<sub>6</sub>]<sup>5-</sup> domains, and the connection of larger [FeCl<sub>6</sub>]<sup>3-</sup>-[AgCl<sub>6</sub>]<sup>5-</sup> domains leads to segregated Fe<sup>3+</sup>-rich phases. The  $E_g$  of Cs<sub>2</sub>AgInCl<sub>6</sub> was tuned from 2.8 to 1.6 eV *via* Fe<sup>3+</sup>-alloying.

The second approach to tune  $E_g$  of double perovskite is to adjust the physical structure. First-principles calculations indicated that changing the order of Ag<sup>+</sup> and Bi<sup>3+</sup> in space can significantly reduce  $E_g$ . When the arrangement of Ag<sup>+</sup> and

Fig. 1. (Color online) Tuning E<sub>g</sub> of double perovskites.

Bi<sup>3+</sup> was completely disordered, the E<sub>g</sub> could be reduced to 0.44 eV<sup>[17]</sup>. Gao *et al.*<sup>[18]</sup> reported that through thermally-induced defects, as the temperature increased, the color of Cs<sub>2</sub>AgBiBr<sub>6</sub> single crystal and film can change from red to black, the E<sub>g</sub> decreased, but the original color of the film recovered after cooling. The finite-temperature molecular dynamics simulations indicated the synergistic effect of the incongruous bond lengths ( $R_{Ag-Br}$  and  $R_{Bi-Br}$ ) fluctuations and the related electron-phonon coupling, as well as the special spin-orbit coupling effect, were the cause for the thermochromism. Gao *et al.*<sup>[19]</sup> increased the disorder degree of [AgBr<sub>6</sub>] and [BiBr<sub>6</sub>] octahedral by adjusting the crystallization speed of Cs<sub>2</sub>AgBiBr<sub>6</sub>. As the temperature increases, the disorder degree gradually increases, the lattice shrinks, initially leading to the formation of isolated defect states in the forbidden band, and finally a series of defect states, and reduced E<sub>g</sub> (60 °C, 1.98 eV; 150 °C, 1.72 eV). And this reduced E<sub>g</sub> can keep stable at room temperature. Zou *et al.*<sup>[20]</sup> found that high pressure can also significantly reduce E<sub>g</sub> of Cs<sub>2</sub>AgBiBr<sub>6</sub> single crystal. Under 15 GPa pressure, the E<sub>g</sub> was reduced from 2.2 to 1.7 eV. When the pressure was released, the E<sub>g</sub> was relatively lower than that at atmospheric pressure.

In summary, for double perovskite Cs<sub>2</sub>AgBiBr<sub>6</sub>, the effect of A-site doping on E<sub>g</sub> is not obvious, the stability of X-site doping is intractable, and only B-site doping can significantly tune E<sub>g</sub>. Changing the order of Ag<sup>+</sup> and Bi<sup>3+</sup> in space is much

effective for reducing E<sub>g</sub> (Table 2). We need further study E<sub>g</sub>-narrowing mechanism of double perovskites and find effective methods to realize it.
