（Received 31 March 2020；revised manuscript received 20 May 2020；accepted manuscript online 25 May 2020）
Up to now，at least 806 carbon allotropes have been proposed theoretically．Three interesting carbon allotropes （named Pbam－32，P6／mmm，and $I \overline{4} 3 \mathrm{~d}$ ）were recently uncovered based on a random sampling strategy combined with space group and graph theory．The calculation results show that they are superhard and remarkably stable compared with previously proposed metastable phases．This indicates that they are likely to be synthesized in experiment．We use the factor group analysis method to analyze their $\Gamma$－point vibrational modes．Owing to their large number of atoms in primitive unit cells（ 32 atoms in Pbam－32， 36 atoms in P6／mmm，and 94 atoms in $I \overline{4} 3 d$ ），they have many Raman－and infrared－ active modes．There are 48 Raman－active modes and 37 infrared－active modes in Pbam－32， 24 Raman－active modes and 14 infrared－active modes in $P 6 / \mathrm{mmm}$ ，and 34 Raman－active modes and 35 Raman－and infrared－active modes in $I \overline{4} 3 \mathrm{~d}$ ．Their calculated Raman spectra can be divided into middle frequency range from $600 \mathrm{~cm}^{-1}$ to $1150 \mathrm{~cm}^{-1}$ and high frequency range above $1150 \mathrm{~cm}^{-1}$ ．Their largest infrared intensities are $0.82,0.77$ ，and $0.70(\mathrm{D} / \AA)^{2} / \mathrm{amu}$ for $P b a m, P 6 / \mathrm{mmm}$ ，and $I \overline{4} 3 d$ ，respectively．Our calculated results provide an insight into the lattice vibrational spectra of these $\mathrm{sp}^{3}$ carbon allotropes and suggest that the middle frequency Raman shift and infrared spectrum may play a key role in identifying newly proposed carbon allotropes．

## 1．Introduction

The unique ability of carbon element to form $\mathrm{sp}, \mathrm{sp}^{2}$ ，and $\mathrm{sp}^{3}$ hybridized bonds leads to a large number of allotropes．${ }^{[1]}$ Among them，diamond（three dimensions），graphene（two di－ mensions），carbon nanotubes（one dimension），and fullerene （zero dimension）have been widely investigated in various ap－ plications．They can be insulator，semiconductor，semimetal， metal or even superconductor．${ }^{[2,3]}$ This made carbon allotrope prediction to be a very active field of investigation in recent years．${ }^{[4-7]}$ As shown in Samara Carbon Allotrope Database， at least 522 three－dimensional carbon allotropes have been proposed based on a variety of sophisticated algorithms．${ }^{[1]}$ Among these newly proposed carbon allotropes，some of them （C20－sc，C21－sc，C22－sc，${ }^{[8,9]} \mathrm{M}$ carbon，${ }^{[6,10]} \mathrm{S}$ carbon，${ }^{[11,12]}$ T carbon，${ }^{[13,14]} \mathrm{V}$ carbon，${ }^{[15]}$ and Z carbon ${ }^{[16]}$ ）are reported to be obtained in experiment．However，not all experiments can be explained by these proposed carbon allotropes．For exam－ ple，diamond anvil can even be indented by cold－compressed graphite，but its structure is still totally unresolved．${ }^{[17]}$

DOI：10．1088／1674－1056／ab9613

Multi－scale computation simulation is often used for searching and investigating new materials．${ }^{[18]}$ The energy sur－ face of carbon is very complex，especially for crystals with large unit cell．In order to meet this challenge，Shi et al．${ }^{[5]}$ and He et al．${ }^{[7]}$ uncovered 284 carbon allotropes with a random sampling strategy combined with space group and graph theory．This method enables the search for large－size and complex carbon allotropes up to 100 carbon atoms per unit cell．After a systematical search for large－size $\mathrm{sp}^{3}$ car－ bon crystals，three complex low energy tetrahedral carbon allotropes（Pbam－32，P6／mmm，and $I \overline{4} 3 \mathrm{~d}$ ）were uncovered recently，and the calculated phonon dispersions and elastic constants show that they are dynamically and mechanically stable．${ }^{[7]}$ There are 32,36 ，and 94 atoms in their primitive unit cells，respectively and their energy relative to diamond is $0.10 \mathrm{eV} /$ atom for $\operatorname{Pbam}-32,0.13 \mathrm{eV} /$ atom for $P 6 / \mathrm{mmm}$ ， $0.14 \mathrm{eV} /$ atom for $I \overline{4} 3 d$ ．The relative energy of other metastable carbon allotropes is $0.11 \mathrm{eV} /$ atom for C －carbon， $0.14 \mathrm{eV} /$ atom for T12， $0.15 \mathrm{eV} /$ atom for Z－carbon， $0.15 \mathrm{eV} /$ atom for P －

[^0]carbon, $0.16 \mathrm{eV} /$ atom for O -carbon, $0.18 \mathrm{eV} /$ atom for $\mathrm{W}-\mathrm{c}$ arbon, $0.19 \mathrm{eV} /$ atom for M-carbon, $0.19 \mathrm{eV} /$ atom for F-carbon, $0.21 \mathrm{eV} /$ atom for X -carbon, and $0.23 \mathrm{eV} /$ atom for Bct-C4. Therefore, these three newly proposed carbon allotropes are remarkably stable compared with those metastable phases previously proposed, which indicates that they are very likely to be synthesized in experiment. Furthermore, the $I \overline{4} 3 d$ structure has the widest electronic band gap of 7.25 eV in carbon allotrope family.

In the investigation of carbon materials, Raman spectrum, as a fast, cheap and nondestructive method, plays a key role in identifying them. ${ }^{[19-23]}$ For example, the D, G, and 2D peaks of graphene, ${ }^{[22,24-26]}$ the interlay shearing and breathing mode of multilayer graphene, ${ }^{[20,21,27]}$ the breathing mode of carbon nanotube ${ }^{[28,29]}$ provide unique fingerprint of them. Besides Raman spectrum, infrared spectrum is also widely used to characterize carbon nanotube, ${ }^{[30]}$ graphite, ${ }^{[31]}$ graphene, ${ }^{[32]}$ and even diamond under electric field. ${ }^{[33]}$ In order to investigate the first order Raman and infrared spectra of these three newly proposed carbon allotropes, we perform factor group analysis and first-principles calculation and obtain their Raman tensor and infrared intensity of $\Gamma$-point vibrational modes.

## 2. Calculation method

All the density-functional calculation was obtained under the framework of the local density approximation (LDA) as implemented in the Quantum Espresso package. ${ }^{[34]}$ The
wave function was expanded in a plane-wave basis set with an energy cutoff of $100 \mathrm{Ry}(1 \mathrm{Ry}=13.6056923(12) \mathrm{eV})$. The $k$-points in the Brillouin zone of the primitive unit cell were sampled on $4 \times 4 \times 10$ mesh for Pbam- $32,4 \times 4 \times 10$ mesh for $P 6 / \mathrm{mmm}$, and $4 \times 4 \times 4$ mesh for $I \overline{4} 3 \mathrm{~d}$. The MonkhorstPack $k$-mesh was employed for the Brillouin-zone integration. The norm-conserving pseudopotential was used to represent the electron-ion interaction. ${ }^{[35]}$ The $\Gamma$-point vibrational frequency, Raman activity, and infrared intensity were calculated within the framework of density functional perturbation theory. ${ }^{[36-40]}$

## 3. Results and discussion

### 3.1. Crystal structure and symmetry

The crystal structure of Pbam-32, P6/mmm, and I $\overline{4} 3 \mathrm{~d}$ are depicted in Fig. 1. The Pbam-32 has 32 carbon atoms in its primitive unit cell with a two-fold ration axis along $a_{3}$ direction. As shown in Fig. 1(a), the primitive unit cell is composed of fivefold, sixfold and sevenfold topological carbon rings. As it can be easily transformed from wrinkled graphite, Pbam32 is a good candidate product of cold compressed graphite. The $P 6 / \mathrm{mmm}$ has 36 carbon atoms in its primitive unit cell with a six-fold ration axis along $a_{3}$ direction. As depicted in Fig. 1(b), the fivefold and sixfold carbon rings arrange around the center eightfold carbon rings in $P 6 / \mathrm{mmm}$. Unlike Pbam32, $P 6 / \mathrm{mmm}$ cannot be obtained by simply transformation from graphite. However, it can be acquired from well-arranged array of certain carbon nanotubes.

Fig. 1. Primitive cell of (a) Pbam-32, (b) P6/mmm, and (c) I $\overline{4} 3 d$. They are composed of tetrahedra network, which is the characteristic of $\mathrm{sp}^{3}$ hybridization. The numbers of panels (a) and (b) refer to fivefold, sixfold, sevenfold, and eightfold topological carbon rings.

As shown in Fig. 1(c), the structure of $I \overline{4} 3 d$ is cubic, containing 94 carbon atoms in its primitive unit cell. Due to its complexity, $I \overline{4} 3 d$ can be obtained neither from graphite nor from carbon nanotubes directly. It might be synthesized in explosive shock experiment. It can be seen from Fig. 1 that the carbon atoms of Pbam-32 form tetrahedron network, and so do those of $P 6 / \mathrm{mmm}$ and $I \overline{4} 3 \mathrm{~d}$. A carbon atom has six electrons with a $(1 \mathrm{~s})^{2}(2 \mathrm{~s})^{2}(2 \mathrm{p})^{2}$ configuration. The energy difference between the $2 s$ - and the $2 p$-states is small. Therefore, in molecular or crystal, it is possible to excite one carbon electron from the 2 s -state into the 2 p -state. This results in a special state: one s-orbital and three p-orbitals. These four orbitals form the $\mathrm{sp}^{3}$ hybridization. The direction of the $\mathrm{sp}^{3}$ hybridization makes a carbon form a tetrahedral assembly with its neighbors, like diamond. It is the characteristic of $\mathrm{sp}^{3}$ hybridization. As Pbam-32 and $P 6 / \mathrm{mmm}$ have the inversion center symmetry, they have neither piezoelectric nor second harmonic generation response. ${ }^{[41,42]}$ The calculated lattice parameters and relative energy values are listed in Table 1.

Their $\Gamma$-point vibrational modes are classified with the factor group analysis method. ${ }^{[43]}$ Owing to the inversion
center symmetry, the vibrational modes of Pbam-32 and $P 6 / \mathrm{mmm}$ are either ' g ' mode or ' u ' mode. All the optical vibrational modes at $\Gamma$-point are listed in Table 2. Owing to its low symmetry, Pbam- 32 has only non-degenerate modes. Therefore, it has $96(3 \times 32)$ non-degenerate vibrational modes at $\Gamma$ point. There are three translational modes $\left(B_{1 u}, B_{2 u}\right.$, and $\left.B_{3 u}\right)$ among them. The other 93 vibrational modes are optical modes. There are 48 Ramanactive modes $\left(16 \mathrm{~A}_{\mathrm{g}}+16 \mathrm{~B}_{1 \mathrm{~g}}+8 \mathrm{~B}_{2 \mathrm{~g}}+8 \mathrm{~B}_{3 \mathrm{~g}}\right)$, 37 infrared-active modes $\left(7 \mathrm{~B}_{1 \mathrm{u}}+15 \mathrm{~B}_{2 \mathrm{u}}+15 \mathrm{~B}_{3 \mathrm{u}}\right)$, and 8 silent modes $\left(8 \mathrm{~A}_{\mathrm{u}}\right)$. Owing to the six-fold rotation symmetry, $P 6 / \mathrm{mmm}$ has doubly degenerate modes. It has one non-degenerate translational mode $\left(\mathrm{A}_{2 \mathrm{u}}\right)$ and one doubly degenerate translational mode $\left(\mathrm{E}_{1 \mathrm{u}}\right)$. Besides, it has 24 Raman-active modes $\left(6 \mathrm{~A}_{1 \mathrm{~g}}+6 \mathrm{E}_{1 \mathrm{~g}}+12 \mathrm{E}_{2 \mathrm{~g}}\right)$, 14 infrared-active modes $\left(3 \mathrm{~A}_{2 \mathrm{u}}+11 \mathrm{E}_{1 \mathrm{u}}\right)$, and 32 silent modes $\left(2 A_{1 u}+6 A_{2 g}+4 B_{1 g}+2 B_{2 g}+6 B_{1 u}+6 B_{2 u}+6 \mathrm{E}_{2 \mathrm{u}}\right)$. Owing to its high symmetry, $I \overline{4} 3 d$ has triply degenerate mode. It has a triply degenerate translational mode $\mathrm{T}_{2}$. Besides, it has 34 Raman-active modes $\left(11 \mathrm{~A}_{1}+23 \mathrm{E}\right)$ and 47 silent modes $\left(12 \mathrm{~A}_{2}+35 \mathrm{~T}_{1}\right)$. Unlike the other two crystals, $I \overline{4} 3 d$ has $35 \mathrm{~T}_{2}$ modes, which are both Raman- and infrared-active.

Table 1. Calculated crystal parameters of Pbam-32, P6/mmm, and $I \overline{4} 3 \mathrm{~d}$. Integer fractions represent atomic positions fixed by symmetry. Their energy values relative to diamond are listed in the last column. Data with * is cited from Ref. [7].

### 3.2. Calculated Raman spectrum and infrared intensity

In order to investigate Raman spectra, we firstly calculate their non-resonant Raman activities with DFT and list them in Table 3. After that, the first-order non-resonant differential Raman cross section of the stocks component is calculated from the following equation: ${ }^{[44]}$

$$
\begin{align*}
\frac{\mathrm{d} \sigma}{\mathrm{~d} \Omega}= & \left(\frac{2 h \pi^{2}}{c^{4}}\right)\left|\hat{e}_{\mathrm{s}} \frac{\partial \tilde{\alpha}}{\partial Q} \hat{e}_{\mathrm{I}}\right|^{2} \frac{\left(v_{\mathrm{i}}-v_{\mathrm{p}}\right)^{4}}{v_{\mathrm{p}}} \\
& \times\left(1+\frac{1}{\exp \left(h v_{\mathrm{p}} / k T\right)-1}\right), \tag{1}
\end{align*}
$$

where $\hat{e}_{\mathrm{I}}$ and $\hat{e}_{\mathrm{S}}$ are the electric field unit vectors of incident light and scattered light, respectively, $\tilde{\alpha}$ is the polarizability tensor, $v_{\mathrm{p}}$ and $Q$ are the phonon frequency and its normalmode coordinate, respectively, $v_{\mathrm{i}}$ and $\left(v_{\mathrm{i}}-v_{\mathrm{p}}\right)$ are the incident light frequency and scattered light frequency, respectively, and the last term on the right-hand side, $1+\left[\exp \left(h v_{\mathrm{p}} / k T\right)-1\right]^{-1}$ is the Bose-Einstein statistical factor, in which $T$ is the temperature. According to the above equation, we show the Raman spectrum at 300 K with $532-\mathrm{nm}$ excitation light in Fig. 2. As the Raman spectrum of diamond usually serves as an external standard, ${ }^{[45]}$ we give the Raman spectrum of diamond at the last line of Fig. 2.

The Raman spectra in Fig. 2 can be divided into two parts: the left middle frequency range below $1150 \mathrm{~cm}^{-1}$ and the right high frequency range above $1150 \mathrm{~cm}^{-1}$. Except for diamond, the other 3 carbon allotropes have obvious peaks in the middle frequency range. The Raman spectrum of Pbam-32, $P 6 / \mathrm{mmm}$, and $I \overline{4} 3 \mathrm{~d}$ look more complicated than that of BctC4, C-carbon, F-carbon, M-carbon, O-carbon, P-carbon, T12, W-carbon, X-carbon, and Z-carbon. ${ }^{[23]}$ It originates from the atom number of primitive unit cell. It is 2 atoms in diamond, 4 atoms in Bct-C4, 8 atoms in F-carbon, M-carbon, and Zcarbon, 12 atoms in C-carbon and T12, and 16 atoms in O carbon, P-carbon, W-carbon, and X-carbon. However, it is as large as 32 atoms in Pbam-32, 36 atoms in $P 6 / \mathrm{mmm}$, and even 94 atoms in Ibar43d. The larger the atom number, the more the peaks in its Raman spectrum are.

Unlike diamond, these three newly proposed carbon allotropes have infrared active modes. Infrared intensity is proportional to $|\partial \boldsymbol{\mu} / \partial Q|^{2}$, where $\boldsymbol{\mu}$ is the electric dipole moment and $Q$ is the normal-mode coordinate. ${ }^{[44]}$ The infrared spectrum of carbon nanotube, ${ }^{[30]}$ graphite, ${ }^{[31]}$ graphene, ${ }^{[32]}$ and even diamond under electric field ${ }^{[33]}$ have been reported in experiment. As Pbam-32, P6/mmm, and $I \overline{4} 3 d$ are $\mathrm{sp}^{3}$ carbon allotropes, their Born effective charges ${ }^{[46]}$ are rather small,
resulting in low infrared intensity. As given in Table 4, the largest infrared intensity is $0.82(\mathrm{D} / \AA)^{2} / \mathrm{amu}$ for $1352 \mathrm{~cm}^{-1}$ of Pbam, $0.77(\mathrm{D} / \AA)^{2} / \mathrm{amu}$ for $1125 \mathrm{~cm}^{-1}$ of $P 6 / \mathrm{mmm}$, and $0.70(\mathrm{D} / \AA)^{2} / \mathrm{amu}$ for $1117 \mathrm{~cm}^{-1}$ of $I \overline{4} 3 d$. They are much smaller than that of ionic crystals. ${ }^{[41]}$ This indicates that the infrared spectrum may play a key role in identifying newly proposed carbon allotropes.

Fig. 2. Calculated Raman spectra of powder sample at 300 K with $532-\mathrm{nm}$ excitation light. There are obvious peaks in the middle frequency region from $600 \mathrm{~cm}^{-1}$ to $1150 \mathrm{~cm}^{-1}$ except for diamond.

Table 4. Calculated frequency and infrared intensity (I.I., in units ( $\mathrm{D} / \AA)^{2} / \mathrm{amu} \times 10^{-2}$ ) of infrared-active mode.

### 3.3. Vibrational modes of principle peaks

As shown in Fig. 2, there are many peaks in the Raman spectra of Pbam-32, P6/mmm, and $I \overline{4} 3 \mathrm{~d}$. In order to give a detailed analysis, we depict the vibrational modes of principle peaks in Figs. 3-5.

Figure 3 shows the vibrational modes of the principle
peaks of Pbam-32. Based on the atom movement directions, the vibrational modes can be divided into two groups. In Fig. 3(g), 3(m), and 3(n) belong to the first group, in which atoms move along the $\boldsymbol{a}_{3}$ direction. In Fig. 3(g), the center carbon atoms of most tetrahedrons move in the same direction as one apical carbon atom and opposite to the other two apical atoms. Therefore, its frequency is relatively low. In

Figs. 3(m) and 3(n), the central carbon atoms of most tetrahedrons move opposite to the three apical carbon atoms. They are similar to the $\mathrm{F}_{2}$ mode of diamond. Therefore, their vibrational frequencies ( $1309 \mathrm{~cm}^{-1}$ for Fig. 3(m) and $1310 \mathrm{~cm}^{-1}$ for Fig. 3(n)) are close to the vibrational frequency of diamond $F_{2}$ mode ( $1333 \mathrm{~cm}^{-1}$ ). The others belong to the second group, in which atoms move in the $\boldsymbol{a}_{1}$ and $\boldsymbol{a}_{2}$ planes. In Fig. 3(c), the center (corner) atom pairs of the unit cell move in the oppo-
site directions, and the contributions of other atoms are small. In Fig. 3(d), the contributions of center and corner atom pairs of the unit cell still dominate the mode. The contributions of other atoms increase relative to the scenario in Fig. 3(c). In Fig. 3(e), carbon atoms move almost along the $\boldsymbol{a}_{2}$ direction, and most atoms move opposite to their nearest neighbors. The vibrational modes of Figs. 3(o)-3(q) are dominated by a few specific atom pairs.

Fig. 3. Vibrational modes of principle peaks of Pbam-32.

Fig. 4. Vibrational modes of principle peaks of $P 6 / \mathrm{mmm}$.

As $P 6 / \mathrm{mmm}$ has six-fold symmetry, the vibrational modes in Fig. 4 look more regular than those in Fig. 3. In Fig. 4(g), all atoms move along the $a_{3}$ direction. The mode in Fig. $4(\mathrm{~g})$ is similar to the vibrational mode of Fig. 3(g). Except for the mode in Fig. 4(g), the other modes in Fig. 4 vibrate in the $\boldsymbol{a}_{1}$ and $\boldsymbol{a}_{2}$ planes. In Figs. 4(b), 4(c), and 4(h), the regular sixfold carbon rings in the unit cell corners vibrate like a breathing mode: ${ }^{[23,29]}$ all atoms of the sixfold ring move toward the ring center. In Fig. 4(b), the regular sixfold carbon rings both at four corners and in the center of the unit cell vibrate in phase like a breathing mode. In Fig. 4(c), the regular sixfold rings at the corners and the eightfold rings in the center of unit cell vibrate in phase like a breathing mode. In Fig. 4(f), the atoms of the regular sixfold rings vibrate toward each other. It is similar to the fully symmetric vibrational mode of graphene at $K$ point. The vibrational mode of

Fig. 4(k) looks similar to Fig. 4(f). In Fig. 4(k), it is the atoms of eightfold rings that vibrate toward each other, which differs from the atoms of the sixfold rings in Fig. 4(f). In Fig. 4(j), the center atoms in most of tetrahedrons move opposite to their apical atoms. It is similar to the $\mathrm{F}_{2}$ mode of diamond. Therefore, its vibrational frequency ( $1314 \mathrm{~cm}^{-1}$ ) is close to that of diamond ( $1333 \mathrm{~cm}^{-1}$ ).

The vibrational modes of $I \overline{4} 3 d$ depicted in Fig. 5 are complicated. Although $I \overline{4} 3 d$ belongs to the high-symmetry point group $T_{d}$, there are 94 carbon atoms in its primitive unit cell. Consequently, the vibrational modes depicted in Fig. 5 are complicated and irregular. They do not show clear and distinct pattern. All the detailed information about vibrational modes of Pbam-32, $P 6 / \mathrm{mmm}$, and $I \overline{4} 3 \mathrm{~d}$ can be found in supplementary data.

Fig. 5. Vibrational modes of principle peaks for $I \overline{4} 3 d$. We only give carbon wireframe here for clarity.

### 3.4. Electronic band structures

In order to to deepen the understanding of these three new carbon allotropes, we calculate their electronic band structures and show them in Fig. 6. As shown in Fig. 6, the Pbam-32, P6/mmm, and $I \overline{4} 3 d$ have obvious band gaps, which are 4.8, 3.4, and 6.1 eV , respectively. For the occupied states from -21 to 0 , they are composed of 2 s and 2 p states. Owing to the $\mathrm{sp}^{3}$ bonds, there are obvious energy dispersion in Figs. 6(a)-6(c). Compared with Figs. 6(a) and 6(b), figure 6(c) is a little messy. This is because there are 32 atoms in the primitive unit cell of Pbam-32, 36 atoms in $P 6 / \mathrm{mmm}$, and 94 atoms in $I \overline{4} 3 \mathrm{~d}$. The atom number in $I \overline{4} 3 \mathrm{~d}$ is about three times that of Pbam-32 and $P 6 / \mathrm{mmm}$. This large number of atoms brings about the fact that there are more points in the band structure of $I \overline{4} 3 d$ for a special $k$ point.

Fig. 6. Calculated electronic band structures of (a) Pbam-32, (b) $P 6 / \mathrm{mmm}$, and (c) $I \overline{4} 3 \mathrm{~d}$. The energy of the highest occupied state is set to be zero.

## 4. Conclusions

By the factor group analysis method, we classify the vibrational modes as Pbam-32, $P 6 / \mathrm{mmm}$, and $I \overline{4} 3 \mathrm{~d}$. Owing to the large atom numbers in their primitive unit cells, these three carbon allotropes have many Raman and infrared active modes. There are 48 Raman-active modes $\left(16 \mathrm{~A}_{\mathrm{g}}+16 \mathrm{~B}_{1 \mathrm{~g}}+8 \mathrm{~B}_{2 \mathrm{~g}}+8 \mathrm{~B}_{3 \mathrm{~g}}\right)$ and 37 infrared-active modes $\left(7 \mathrm{~B}_{1 \mathrm{u}}+15 \mathrm{~B}_{2 \mathrm{u}}+15 \mathrm{~B}_{3 \mathrm{u}}\right)$ in Pbam-32, 24 Raman-active modes $\left(6 \mathrm{~A}_{1 \mathrm{~g}}+6 \mathrm{E}_{1 \mathrm{~g}}+12 \mathrm{E}_{2 \mathrm{~g}}\right)$ and 14 infrared-active modes $\left(3 \mathrm{~A}_{2 \mathrm{u}}+11 \mathrm{E}_{1 \mathrm{u}}\right)$ in $P 6 / \mathrm{mmm}$, and 34 Raman-active modes $\left(11 \mathrm{~A}_{1}+23 \mathrm{E}\right)$ and 35 Raman- and infrared-active modes $\left(35 \mathrm{~T}_{2}\right)$ in $I \overline{4} 3 d$. After that, we calculate their $\Gamma$-point phonon frequencies. We find that most of frequencies of the Ramanactive modes are far below the Raman frequency of diamond ( $1333 \mathrm{~cm}^{-1}$ ) and graphite ( $1350 \mathrm{~cm}^{-1}$ and $1586 \mathrm{~cm}^{-1}$ ). Furthermore, we calculate the first-order Raman and infrared intensities. Their Raman spectra can be divided into two ranges: middle frequency range from $600 \mathrm{~cm}^{-1}$ to $1150 \mathrm{~cm}^{-1}$ and high frequency range above $1150 \mathrm{~cm}^{-1}$. Their largest infrared intensities are $0.82,0.77$, and $0.70(\mathrm{D} / \AA)^{2} / \mathrm{amu}$ for Pbam-32, $P 6 / \mathrm{mmm}$, and $I \overline{4} 3 d$, respectively. This indicates that the middle frequency Raman shift and infrared spectrum may play a key role in identifying newly proposed carbon allotropes.
